The Company

Olympus Corporation is an international company operating in industrial, medical and consumer markets, specializing in optics, electronics and precision engineering. Olympus instruments contribute to the quality of products and add to the safety of infrastructure and facilities.

Olympus is a world-leading manufacturer of innovative nondestructive testing instruments that are used in industrial and research applications ranging from aerospace, power generation, petrochemical, civil infrastructure and automotive to consumer products. Leading edge testing technologies include ultrasound, ultrasound phased array, eddy current, and eddy current array. Its products include flaw detectors, thickness gages, in-line systems, automated systems, industrial scanners, pulser-receivers, probes, transducers, and various accessories. Olympus is also a distributor of remote visual inspection instruments and high speed video cameras in the Americas.

Olympus is based in Waltham, Massachusetts, USA, the company has sales and service centers in all principal industrial locations worldwide. Visit www.olympus-ims.com for applications and sales assistance.

Panametrics® Ultrasonic Transducers

Panametrics ultrasonic transducers are available in more than 5000 variations in frequency, element diameter, and connector styles. With more than forty years of transducer experience, Olympus has developed a wide range of custom transducers for special applications in flaw detection, weld inspection, thickness gaging, and materials analysis.

How to select frequency

As the frequency increases, the wavelength decreases, which allows for smaller defect resolution and greater penetration into the workpiece being tested. There are two main methods for determining the appropriate frequency for a given application:

1. Calculate the required resolution and determine the smallest defect size that must be detected. Then calculate the required wavelength to detect the defect.
2. Calculate the maximum penetration depth required and determine the largest defect size that must be detected. Then calculate the required wavelength to detect the defect.

Is element diameter important?

The element diameter is an important factor to consider when choosing the ultrasonic element diameter. Beam spread, or the angle of divergence of the ultrasonic beam, is dependent on the element diameter. The larger the element diameter, the narrower the beam spread.

Why does bandwidth matter?

The bandwidth of an ultrasonic transducer is the range of frequencies over which it can produce a signal. A narrowband transducer has a narrow bandwidth, while a broadband transducer has a wider bandwidth. The choice of bandwidth depends on the application. For example, a narrowband transducer is better suited for flaw detection, while a broadband transducer is better suited for thickness measurement.

Is wave mode important?

A wave mode is a specific type of ultrasonic wave that is generated by a transducer. There are several different types of wave modes, including longitudinal, shear, and Rayleigh waves. Each wave mode has its own unique properties and applications.

What does focusing do?

Focusing is a process where the sound waves are concentrated into a narrow beam. This allows for better resolution and improved detection of small defects. Focusing is achieved by using a lens or a curved surface to direct the sound waves towards a specific point.

What effect does nearfield have?

The nearfield is the region of a transducer where the sound waves are scattered in all directions. This region is characterized by a high intensity of sound waves, which can lead to artifacts in the signal. The size of the nearfield is determined by the following formula:

$$BD = \frac{c}{4f}$$

Where:
BD = Beam length
c = Speed of sound
f = Frequency
D = Element diameter

Probe Types

- Dual:** This probe uses two separate transducers for emitting and receiving ultrasonic signals. Applications include flaw detection, thickness measurement, and non-destructive testing.
- Contact:** This probe is used for inspecting materials with a hard surface. The transducer is held in contact with the surface, allowing for high resolution and deep penetration.
- Angle Beam:** This probe is used for inspecting materials with a hard surface. The transducer is held at an angle to the surface, allowing for high resolution and deep penetration.
- Delay Line:** This probe is used for inspecting materials with a hard surface. The transducer is held at an angle to the surface, allowing for high resolution and deep penetration.
- Immersion:** This probe is used for inspecting materials with a hard surface. The transducer is held at an angle to the surface, allowing for high resolution and deep penetration.

Ultrasonic Transducers Technical Notes	42

Transducer Selection

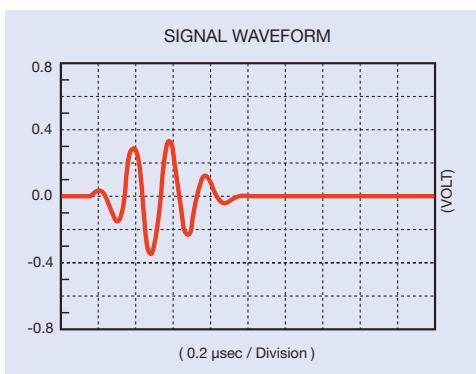

The transducer is one of the most critical components of any ultrasonic system. A great deal of attention should be paid to selecting the proper transducer for the application.

The performance of the system as a whole is of great importance. Variations in instrument characteristics and settings as well as material properties and coupling conditions play a major role in system performance.

We have developed three different series of transducers to respond to the need for variety. Each series has its own unique characteristics.

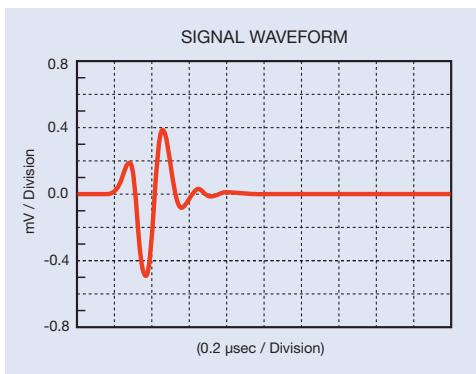

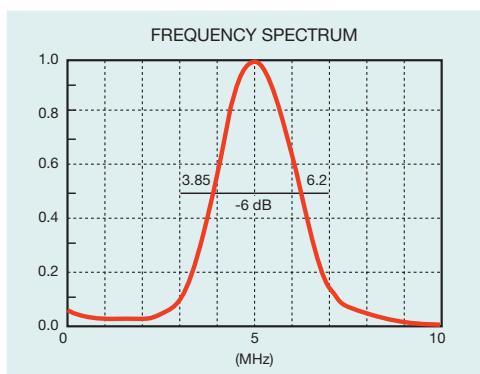

Transducer configuration also has an impact on system performance. Consideration should be given to the use of focused transducers, transducers with wear surfaces that are appropriate for the test material, and the choice of the appropriate frequency and element diameter.

The summaries below provide a general description of the performance characteristics of each transducer series. While these guidelines are quite useful, each application is unique and performance will be dependent on electronics, cabling, and transducer configuration, frequency, and element diameter.

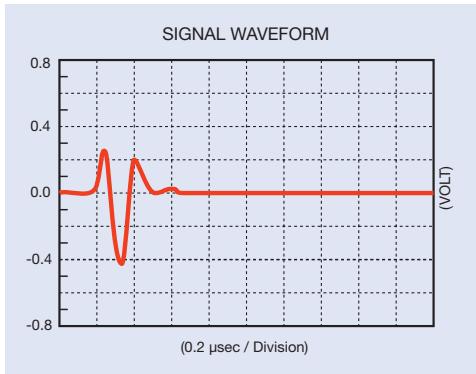

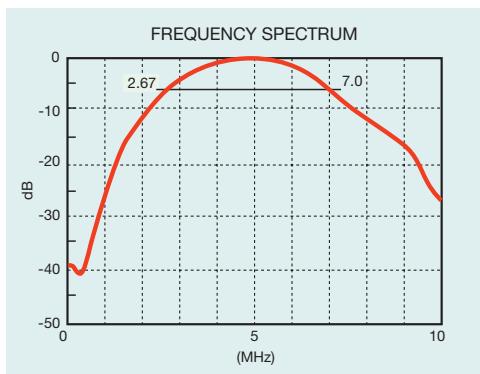

Accuscan™ "S"

The Accuscan S series is intended to provide excellent sensitivity in those situations where axial resolution is not of primary importance. Typically this series will have a longer wave form duration and a relatively narrow frequency bandwidth.

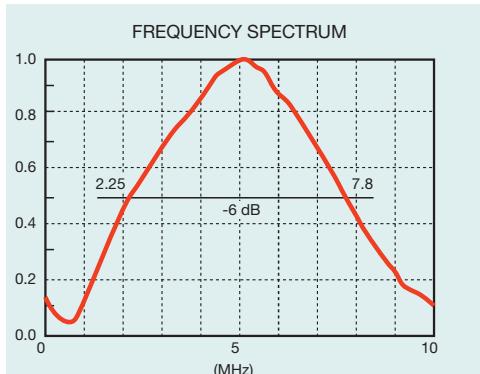

Centrascan™

The piezocomposite element Centrascan Series transducers provide excellent sensitivity with a high signal-to-noise ratio in difficult-to-penetrate materials. They have exceptional acoustic matching to plastics and other low impedance materials.

Videoscan

Videoscan transducers are untuned transducers that provide heavily damped broadband performance. They are the best choice in applications where good axial or distance resolution is necessary or in tests that require improved signal-to-noise in attenuating or scattering materials.

Note: For more information on bandwidth and sensitivity versus resolution, please refer to the "Ultrasonic Transducers Technical Notes" starting on page 42.
Note: For sample test forms of transducers that you are interested in purchasing or if you have questions, please contact us via phone, or e-mail.

Contact Transducers: A contact transducer is a single element transducer, usually generating a longitudinal wave, that is intended for direct contact with a test piece. All contact transducers are equipped with a WC5 wear face that offers superior wear resistance and probe life as well as providing an excellent acoustic impedance match to most metals. Please see "Contact Transducers" on page 8 for more details on longitudinal contact probes or "Normal Incidence Shear Wave Transducers" on page 17 for information on normal incidence shear wave transducers.

Dual Element Transducers: A dual element transducer consists of two longitudinal wave crystal elements (one transmitter and one receiver) housed in the same case and isolated from one another by an acoustic barrier. The elements are angled slightly towards each other to bounce a signal off the backwall of a part in a V-shaped pattern. Dual element transducers typically offer more consistent readings on heavily corroded parts, and can also be used in high temperature environments. Please see "Dual Element Transducers" on page 10 for more information on dual element transducers for flaw detection or "Dual Element Transducers for Thickness Gages" on page 30 for dual element probes for use with Olympus corrosion gages.

Angle Beam Transducers: Angle beam transducers are single element transducers used with a wedge to introduce longitudinal or shear wave sound into a part at a selected angle. Angle beam transducers allow inspections in areas of a part that cannot be accessed by the ultrasonic path of a normal incidence contact transducer. A common use for angle beam transducers is in weld inspection, where a weld crown blocks access to the weld zone of interest for a standard contact transducer and where typical flaw alignment produces stronger reflections from an angled beam. Please see "Angle Beam Transducers and Wedges" on page 12 for additional information on angle beam transducers and wedges. For a detailed explanation of how wedges are designed using Snell's Law please "Focal Length Variations due to Acoustic Velocity and Geometry of the Test Part" on page 49.

Delay Line Transducers: Delay line transducers are single element broadband contact transducers designed specifically to incorporate a short piece of plastic or epoxy material in front of the transducer element. Delay lines offer improved resolution of flaws very near to the surface of a part and allow thinner range and more accurate thickness measurements of materials. Delay lines can be contoured to match the surface geometry of a part and can also be used in high temperature applications. For more information on delay line transducers and delay line options, please see "Delay Line Transducers" on page 18.

Protected Face Transducers: Protected face transducers are single element longitudinal wave transducers with threaded case sleeves, which allow for a delay line, wear cap, or membrane. This makes them extremely versatile and able to cover a very wide range of applications. Protected face transducers can also be used as a direct contact transducer on lower impedance materials such as rubber or plastic for an improved acoustic impedance match. Please see "Protected Face Transducers" on page 20 for more information on protected face transducers and the options available for use with them.

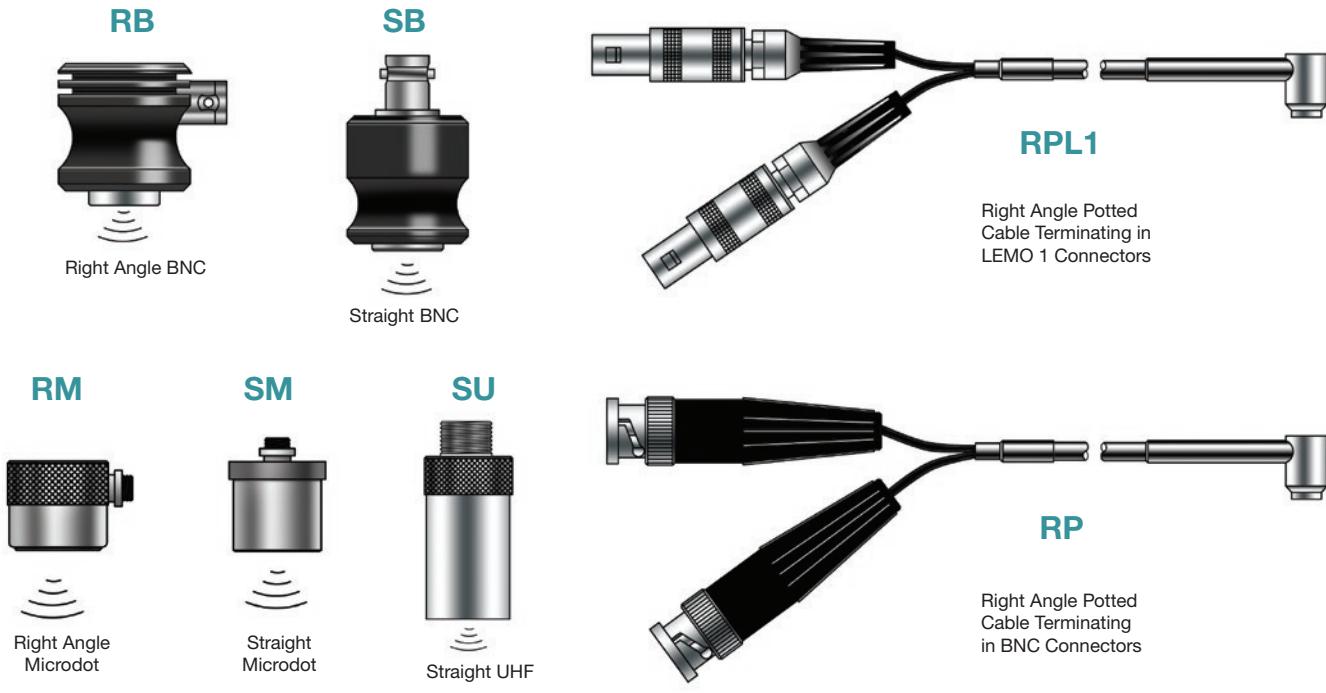

Immersion Transducers: Immersion transducers are single element longitudinal wave transducers, whose wear face is impedance matched to water. Immersion transducers have sealed cases allowing them to be completely submerged under water when used with a waterproof cable. By using water as both a couplant and delay line, immersion transducers are ideal for use in scanning applications where consistent coupling to the part is essential. As an additional option, immersion transducers can also be focused to increase the sound intensity in a specific area and decrease the spot size of the sound beam. For additional information on immersion transducers and in depth explanation of focusing, please see "Immersion Transducers" on page 48.

High Frequency Transducers: High frequency transducers are either delay line or focused immersion transducers and are available in frequencies from 20 MHz to 225 MHz. High frequency delay line transducers are capable of making thickness measurements on materials as thin as 0.0004 in. (0.010 mm) (dependent on material, transducer, surface condition, temperature, and setup), while high frequency focused immersion transducers are ideal for high resolution imaging and flaw detection applications on thin, low attenuation materials such as silicon microchips. For more information on all high frequency transducers, please see "High Frequency Transducers" on page 28.

Test and Documentation

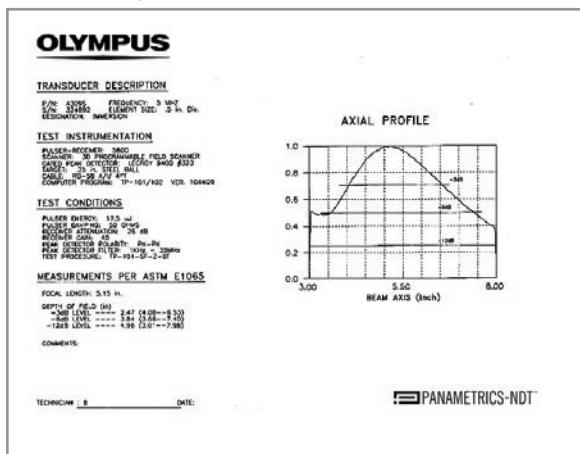

Olympus is an active leader in the development of transducer characterization techniques and has participated in the development of the ASTM-E 1065 Standard Guide for Evaluating Characteristics of Ultrasonic Search Units. In addition, we have performed characterizations according to AWS and EN12668-2. As part of the documentation process, an extensive database containing records of the waveform and spectrum of each transducer is maintained and can be accessed for comparative or statistical studies of transducer characteristics. Our test lab offers a variety of documentation services including waveform and spectrum analysis, axial and transverse beam profiles, and electrical impedance plots.

Please consult us concerning special testing requirements.

Standard Test Forms (TP103)

TP103, or standard test form, records the actual RF waveform and frequency spectrum for each transducer. Each test form has measurements of the peak and center frequencies, upper and lower -6 dB frequencies, bandwidth, and waveform duration according to ASTM-E 1065. The TP103 test form is included at no extra charge on all types of Accuscan, Centrascan, and Videoscan transducers.

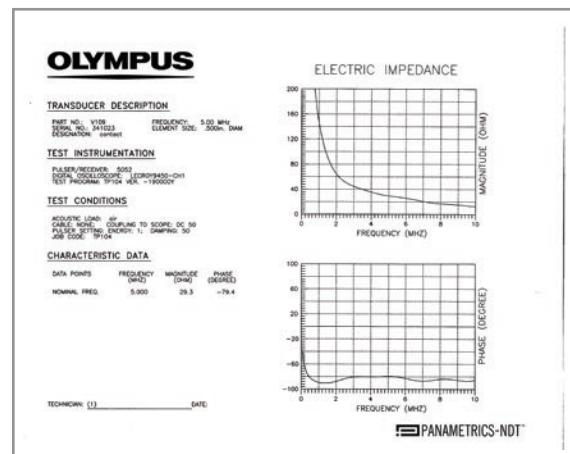

Beam Profiles (TP101)

TP101, or axial beam profile, is created by recording the amplitude of the sound field as a function of distance from the transducer face along the acoustic axis. This provides information on the depth of field, near field, or focal length of the probe. It can be generated from any type of immersion transducer.

Beam Profiles (TP102)

TP102, or transverse beam profile, is created by recording the amplitude of the sound field as the transducer is moved across a ball target in a plane parallel to the transducer face. This is done at a set distance from the transducer, typically at the near field or focal length distance, and in both X and Y axes. It can be generated from any type of immersion transducer.

Electrical Impedance Plots (TP104)

TP104, or electrical impedance plot, provides information on the electrical characteristics of a transducer and how it loads a pulser. The TP104 displays the impedance magnitude versus frequency and the phase angle versus frequency. It can be generated from most types of transducers.

Contact Transducers

A contact transducer is a single element longitudinal wave transducer intended for use in direct contact with a test piece.

Advantages

- Proprietary WC-5 wear plate increases durability, fracture resistance, and wear resistance
- All styles are designed for use in rugged industrial environments
- Close acoustic impedance matching to most metals
- Can be used to test a wide variety of materials

Applications

- Straight beam flaw detection and thickness gaging
- Detection and sizing of delaminations
- Material characterization and sound velocity measurements
- Inspection of plates, billets, bars, forgings, castings, extrusions, and a wide variety of other metallic and non-metallic components
- For continuous use on materials up to 122°F (50°C)

Fingertip Contact

- Units larger than 0.25 in. (6 mm) are knurled for easier grip
- 303 stainless steel case
- Low profile for difficult-to-access surfaces
- Standard configuration is Right Angle and fits Microdot connector

Transducer Dimensions (in inches)		
Nominal Element Size	(A)	(B)
0.50	0.81	0.63
0.25	0.50	0.42

Dual Element Transducers

A dual element transducer consists of two crystal elements housed in the same case, separated by an acoustic barrier. One element transmits longitudinal waves, and the other element acts as a receiver.

For information on transducers for corrosion applications, see "Dual Element Transducers for Thickness Gages" starting on page 30.

Advantages

- Improves near surface resolution
- Eliminates delay line multiples for high temperature applications
- Couples well on rough or curved surfaces
- Reduces direct back-scattering noise in coarse grained or scattering materials
- Combines penetration capabilities of a lower frequency single element transducer with the near surface resolution capabilities of a higher frequency single element transducer
- Can be contoured to conform to curved parts

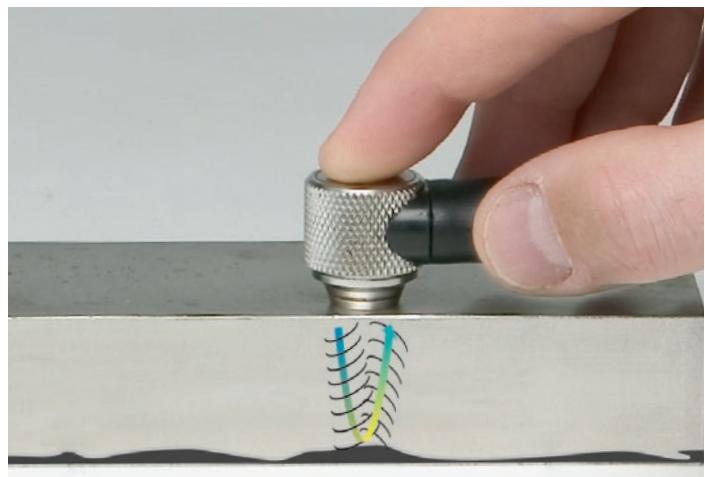

Applications

- Remaining wall thickness measurement
- Corrosion/erosion monitoring
- Weld overlay and cladding bond/disbond inspection
- Detection of porosity, inclusions, cracks, and laminations in castings and forgings
- Crack detection in bolts or other cylindrical objects
- Maximum temperature capability is 800°F (425°C) for 5.0 MHz and below; 350°F (175°C) for 7.5 MHz and 10 MHz. Recommended duty cycle for surface temperatures from 200°F (90°C) to 800°F (425°C) is ten seconds maximum contact followed by a minimum of one minute air cooling (does not apply to Miniature Tip Dual)

Flush Case Duals

- Metal wear ring extends transducer life
- Wear indicator references when transducer face needs resurfacing
- Knurled, 303 stainless steel case
- Replaceable cable design (special dual cables with strain relief available)

Frequency	Nominal Element Size		Transducer Part Numbers
	MHz	in.	mm
1.0	0.50	13	DHC703-RM
2.25	0.50	13	DHC706-RM

	0.25	6	D713-RP	D713-RPL1

Miniature Tip Dual

- Provides better coupling on curved surfaces
- Low profile allows for better access in areas of limited space
- Maximum temperature capability 122°F (50°C)

Frequency	Tip Diameter		Nominal Element Size		Transducer Part Number
MHz	in.	mm	in.	mm	
5.0	0.20	5	0.15	3.8	MTD705

Miniature Tip Dual Cables

- Replaceable cable for all flaw detectors

Cable Part Number	Fits Connector Style
BCLPD-78-5	Dual BNC to Lepra/Con
L1CLPD-78-5	Dual Large LEMO 1 to Lepra/Con
LCLPD-78-5	Dual Small LEMO 00 to Lepra/Con

Extended Range Duals

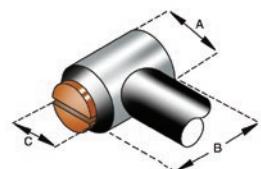

- Shallow roof angles provide greater sensitivity to deep flaws, back walls, and other reflectors, 0.75 in. (19 mm) and beyond in steel
- Can be used for high temperature measurements when delay lines are unacceptable
- High-strength flexible 6 ft (1.8 m) potted cable with BNC connectors

Miniature Tip Dual

Angle Beam Transducers and Wedges

Angle beam transducers are single element transducers used with a wedge to introduce a refracted shear wave or longitudinal wave into a test piece.

Advantages

- Three-material design of our Accupath wedges improves signal-to-noise characteristics while providing excellent wear resistance
- High temperature wedges available for in-service inspection of hot materials
- Wedges can be customized to create nonstandard refracted angles
- Available in interchangeable or integral designs
- Contouring available
- Wedges and integral designs are available with standard refracted angles in aluminum (see "Shear Wave Wedges for Aluminum" on page 15).

Applications

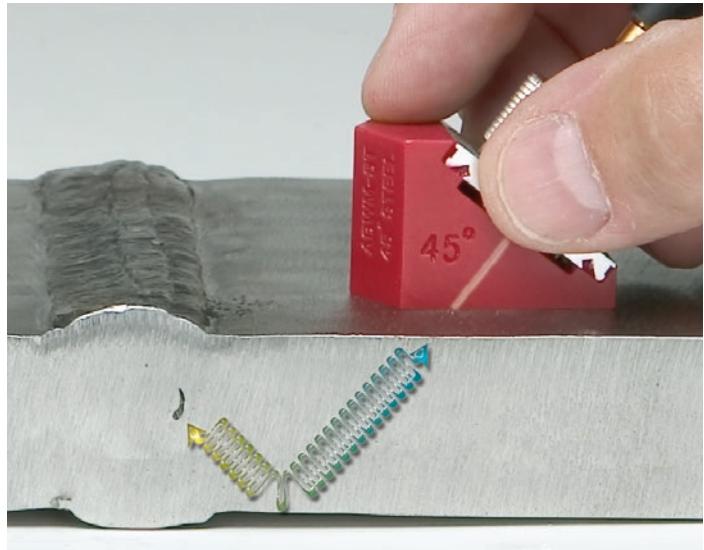

- Flaw detection and sizing
- For time-of-flight diffraction transducers, see "TOFD Transducers" on page 35
- Inspection of pipes, tubes, forgings, castings, as well as machined and structural components for weld defects or cracks

Miniature Screw-In Transducers

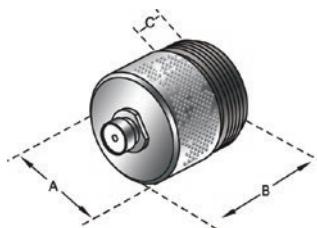

- Screw-in design 303 stainless steel case
- Transducers are color coded by frequency
- Compatible with Short Approach, Accupath, High Temperature, and Surface Wave Wedges

Note: Miniature snap-in transducers available by request.

Miniature angle beam transducers and wedges are used primarily for testing of weld integrity. Their design allows them to be easily scanned back and forth and provides a short approach distance.

Transducer Dimensions
(in inches)

Nominal Element Size	(A)	(B)	(C)	Thread Pitch
0.50	0.71	0.685	0.257	1 ¹ / ₄ - 24
0.375	0.58	0.65	0.257	9 ¹ / ₁₆ - 24
0.25	0.44	0.55	0.22	3 ¹ / ₈ - 32

Short Approach Wedges

- Smallest footprint
- Short approach distance allows for inspection closest to the weld crown

Accupath Wedges

- Small wedge footprint
- Pointed toe design allows transducer rotation even when the nose is touching a weld crown
- Special wedge design for use with 10 MHz transducer

Standard Angle Beam Transducers and Wedges

- Large element size allows for inspection of thicker components and provides a large scanning index
- Transducers available in Accuscan-S, Centrascan, and Videoscan Series
- Accupath and high temperature style wedges available
- Threaded brass screw receptacles ensure firm anchoring of the transducer onto the wedge
- Available in frequencies as low as 0.5 MHz and 1.0 MHz
- Captive screws included with the transducer

Standard Angle Beam transducers and wedges offer a large scanning index, which allows for a shorter scan time on larger test surfaces.

Integral Angle Beam Transducers

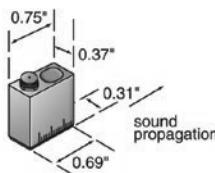

- Durable plastic wear surface extends transducer life and avoids scratching of critical components.
- Small approach distance and overall transducer height provides an excellent choice for limited access applications.
- Superior signal-to-noise characteristics for such small integral transducers
- Finger ring included with Micro-Miniature-RM case style transducers

Contoured Wedges

- Improve coupling on curved surfaces
- When ordering, please specify wedge type, contour orientation, and contour diameter.
- Example Part #: ABWM-4T-45-COD-1.25IN

AWS Wedges and Transducers

- Transducers and wedges meet or exceed the specifications as set forth by the AWS Code Section D1.1.
- Snail wedges use industry accepted hole spacing.
- Captive screws included with the transducer
- Accupath style wedges marked with a five line graticule to assist in locating the beam exit point

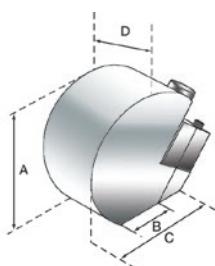

* Wedges are available in standard refracted shear wave angles of 45°, 60° and 70° in steel. Please specify upon ordering.

*Distance between screws (center to center) is 1.062 in.

CDS Wedges

CDS Wedges are used in the "30-70-70" technique for crack detection and sizing. They are compatible with our replaceable miniature screw-in angle beam transducers, making them an economical alternative to other commercially available products. For information on transducers, see "Angle Beam Transducers and Wedges" starting on page 12.

Fits Nominal Element Size	Wedge Part Number

0.375	10

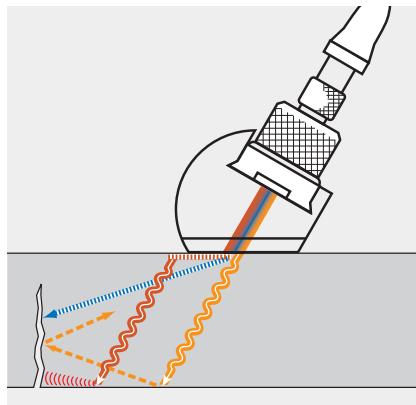

Understanding CDS

The 30-70-70 crack detection technique uses a single element transducer with a CDS wedge for detection and sizing of ID connected cracks. This technique uses a combination of three waves for sizing flaws of different depths.

- An OD creeping wave creates a 31.5 degree indirect shear (red in diagram to the left) wave, which mode converts to an ID creeping wave; this will produce a reflected signal on all ID connected cracks.
- A 30 degree shear wave (orange in diagram to the left) will reflect off the material ID at the critical angle and mode convert to a 70 degree longitudinal wave; a signal will be received by the transducer on mid-wall deep cracks.
- A 70 degree longitudinal wave (blue in diagram to the left) will reflect off the tip of a deep wall crack.

Based on the presence or absence of these three waves, both detection and sizing of ID connected cracks is possible.

Normal Incidence Shear Wave Transducers

Single element contact transducers introduce shear waves directly into the test piece without the use of refracted wave mode conversion.

Advantages

- Generate shear waves which propagate perpendicular to the test surface
- For ease of alignment, the direction of the polarization of shear wave is nominally in line with the right angle connector.
- The ratio of the longitudinal to shear wave components is generally below -30 dB.

Applications

- Shear wave velocity measurements
- Calculation of Young's Modulus of elasticity and shear modulus ("Technical Notes -Normal Incidence Shear Wave Transducers" on page 49)
- Characterization of material grain structure

We recommend the use of our SWC shear wave couplant for general purpose testing.

Direct Contact Series

- WC-5 wear plate increases durability and wear resistance.
- Available in both the Standard and Fingertip case styles
- 303 stainless steel case

Frequency	Nominal Element Size		Transducer Part Numbers

-----	-------------------	------------------------------------------------------------------------------------------------

Delay Line Transducers

A replaceable delay line transducer is a single element contact transducer designed specifically for use with a replaceable delay line.

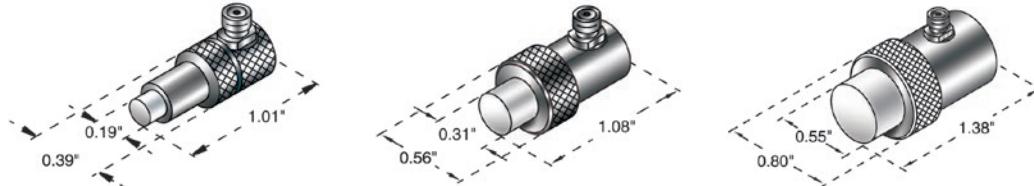

Advantages

- Heavily damped transducer combined with the use of a delay line provides excellent near surface resolution.
- Higher transducer frequency improves resolution.
- Improves the ability to measure thin materials or find small flaws while using the direct contact method
- Contouring available to fit curved parts

Applications

- Precision thickness gaging
- Straight beam flaw detection
- Inspection of parts with limited contact areas
- Replaceable Delay Line Transducers
- Each transducer comes with a standard delay line and retaining ring
- High temperature and dry couple delay lines are available
- Requires couplant between transducer and delay line tip

Permanent Delay Line Transducers with Handle Assembly

These transducers are used to reach into areas of limited access such as adjacent turbine blades. The swivel head improves contact in tight areas.

Frequency	Nominal Element Size		Delay Line Length	Transducer Part Number
MHz	in.	mm	μs	
20	0.125	3	1.5	M2054
20	0.125	3	4.5	M2055
20	0.125	3	4.0	V2034

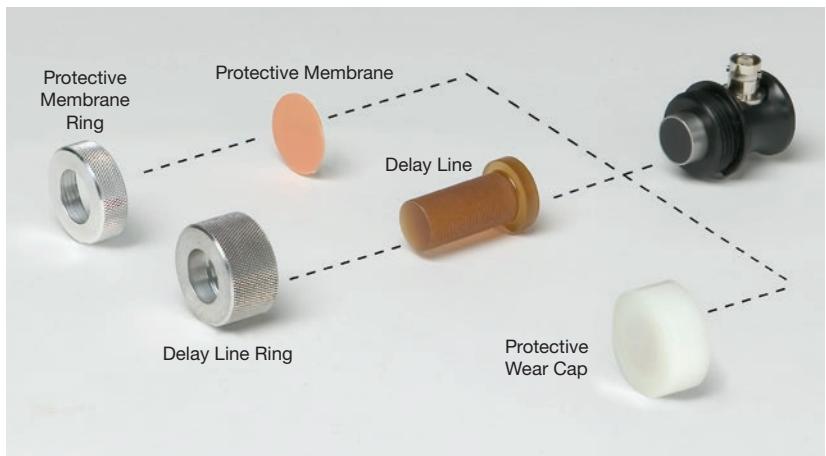

Protected Face Transducers

A protected face transducer is a single element longitudinal wave contact transducer that can be used with either a delay line, protective membrane, or protective wear cap.

Advantages

- Provides versatility by offering removable delay line, protective wear cap, and protective membrane
- When the transducer is used alone (without any of the options), the epoxy wear face provides good acoustic impedance matching into plastics, many composites, and other low impedance materials.
- Cases are threaded for easy attachment to the delay line, protective membrane, and wear cap options.

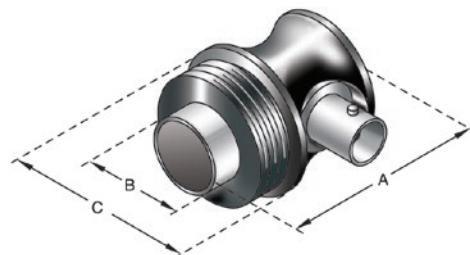

Applications

- Straight beam flaw detection
- Thickness gaging
- High temperature inspections
- Inspection of plates, billets, bars, and forgings

Standard Protected Face

- Comfort Fit sleeves are designed to be easily held and provide steady grip while wearing gloves
- Standard connector style Right Angle BNC (RB); may be available in Straight BNC (SB)
- Delay line, protective membrane, and wear cap options sold separately from the transducer

High Temperature Delay Line Options

- Allows for intermittent contact with hot surfaces*
- Improves near surface resolution
- Contouring of delay lines provides better coupling on curved surfaces.
- Warm temperature delay lines (WTD) can be used for room temperature applications.

Nominal Element Size	Delay Line Retaining Ring	350 °F max. (175 °C)	500 °F max. (260 °C)	900 °F max. (480 °C)
in.	mm			
1.00	25	DRN-3	WTD-3-x	HTD-3-x
0.75	19	DRN-4	WTD-4-x	HTD-4-x
0.50	13	DRN-5	WTD-5-x	HTD-5-x

*Recommended usage cycle is ten seconds maximum contact followed by one minute of air cooling. However, the transducer itself should not be heated above 122°F (50°C).

X = standard delay line lengths, available in ½ in. (13 mm), 1 in. (25 mm), 1-½ in. (38 mm). Specify at time of ordering.

Note: For the delay lines above, a room temperature material longitudinal wave velocity of 0.100 in./μsec ±0.005 in./μsec may be used as an approximation for basic calculations. This value should not be used for engineering design calculations. Contact us for details.

Protective Membrane Option

- Improves coupling on rough or uneven surfaces
- Dry couple to smooth, clean surfaces

Nominal Element Size	Membranes Only*		Membrane Retaining Ring	Kits†
in.	mm	pkg of 12	pkg of 60	
1.50	38	PM-1-12	PM-1-60	MRN-1

Immersion Transducers

An immersion transducer is a single element longitudinal wave transducer with a $\frac{1}{4}$ wavelength layer acoustically matched to water. It is specifically designed to transmit ultrasound in applications where the test part is partially or wholly immersed

Advantages

- The immersion technique provides a means of uniform coupling.
- Quarter wavelength matching layer increases sound energy output.
- Corrosion resistant 303 stainless steel case with chrome-plated brass connectors
- Proprietary RF shielding for improved signal-to-noise characteristics in critical applications
- All immersion transducers, except paintbrush, can be focused spherically (spot) or cylindrically (line) (see "Immersion Transducers" on page 48).
- Customer specified focal length concentrates the sound beam to increase sensitivity to small reflectors.

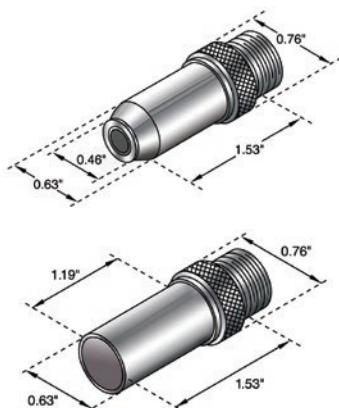

Applications

- Automated scanning
- On-line thickness gaging
- High speed flaw detection in pipe, bar, tube, plate, and other similar components
- Time-of-flight and amplitude based imaging
- Through transmission testing
- Material analysis and velocity measurements

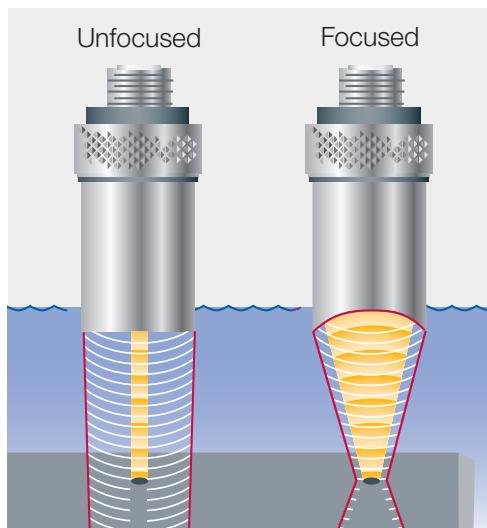

Usage Note: Transducers should not be submerged for periods exceeding 8 hours. Allow 16 hours of dry time to ensure the life of the unit.

Standard Case

- Knurled case with Straight UHF connector (SU)
- Contact us for nonknurled case design and availability of other connector styles.
- Frequencies ranging from 1.0 to 25 MHz

For more technical information, please refer to the following pages:
"Focusing Configurations" on page 48
and "Table 1 - Near Field Distance of Flat Transducers in Water" on page 51

V316-N-SU

Side Looking Immersion Transducers

- Ideal for measuring wall thicknesses of pipe where access to the outer diameter is limited.
- Small outer diameter allows for greater accessibility in tight spaces than standard immersion transducers with reflector mirrors.
- Sound exit point is located at a 90° angle relative to the straight Microdot connector.
- Probe extensions such as the F211 are available to lengthen the standard design.

Part Numbers	Frequency	Nominal Element Size		Focus
		MHz	in.	mm
V3591	10	0.125	3	0.50 OLF
V3343	20	0.125	3	0.50 OLF

Note: All above side looking immersion transducers have straight Microdot connectors.

V3591

V3343

Extra Miniature (XMS) Transducer

The XMS transducer is an extremely small 10 MHz immersion transducer with a 3 mm (0.118 in.) diameter by 3 mm (0.118 in.) long case. This transducer is ideal for extremely tight access areas or for multi-element array flaw detection. The transducer assembly has a special connector attached to the 1 m (38 in.) long potted cable. An adaptor is also available to interface with most commercial ultrasonic equipment.

Frequency	Nominal Element Size		Part Number	Included Adapter
MHz	in.	mm		
10	.080	2	XMS-310-B	BNC
10	.080	2	XMS-310-L	LEMO 01

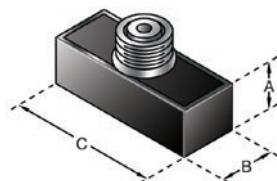

XMS-310-B

Accuscan Paintbrush

- Large scanning index is ideal for inspections of aluminum or steel plate
- Sensitivity uniformity of better than ± 1.5 dB is maintained across the transducer face (sensitivity peaks at the edges are also controlled).

Frequency	Nominal Element Size		Transducer Part Numbers
MHz	in.	mm

† For more information on Standard SU case styles see "Standard Case" on page 22.

RBS-1 Immersion Tank

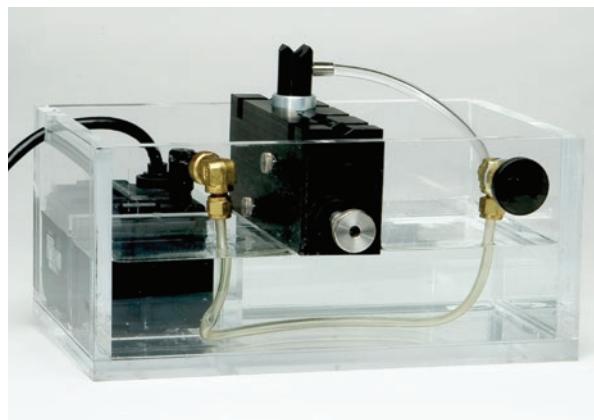

RBS-1 immersion tank is designed to simplify testing measurements using immersion techniques. It consists of a clear acrylic tank, a submersible pump, and a transducer fixture in a single, portable unit. The pump feeds an adjustable stream of water to a bubbler mounted in the fixture, providing a water column to couple sound from an immersion transducer into the test piece. It is ideal for offline thickness measurements on metal, glass, and plastic products such as small containers, pipe or tubing, sheets or plates or machined parts.

Clear Acrylic Tank

- 5.5 H × 8 W × 12 L inches (140 × 200 × 305 mm)
- 0.83 gallon (3.1 liter) capacity

Pump

- Up to 0.25 gallons (0.9 liters) per minute
- 115 or 230 V, 30 watt (voltage range 90 to 135 VAC), 50 to 60 Hz
- Submersible (ground fault interrupter circuit recommended)

Handheld Bubbler Transducer Assembly

Handheld bubbler transducers are available in either 20 MHz (V316B) or 10 MHz (V312B). They are immersion transducers that screw onto a bubbler assembly (B120) which has a replaceable stainless steel tip and a water feed tube. They offer high resolution and easy access inspection of thin materials. The V316B and bubbler combination can resolve thicknesses down to 0.008 in. (0.2 mm).

Spot Weld Transducers

A spot weld transducer is a single element delay line transducer compatible with either a hard tip delay line or captive water column specifically intended for testing the integrity of spot welds.

Advantages:

- Variety of element sizes for testing different size weld nuggets
- Compatible with either hard tip delay line or water column
- Engraved with both inches and millimeters

Applications:

- Automotive, appliances, and other critical industrial spot welds

High Frequency Transducers

High frequency transducers are single element contact or immersion transducers designed to produce frequencies of 20 MHz and greater.

Advantages

- Heavily damped broadband design provides excellent time resolution.
- Short wavelengths for superior flaw resolution capabilities
- Focusing allows for very small beam diameters.
- Frequencies range from 20 MHz to 225 MHz.

Applications

- High resolution flaw detection such as inspection for microporosity or microcracks
- C-scan imaging of surface breaking cracks or irregularities
- Thickness measurements of materials as thin as 0.0004 in. (0.010 mm)*
- Examination of ceramics and advanced engineering materials
- Materials analysis

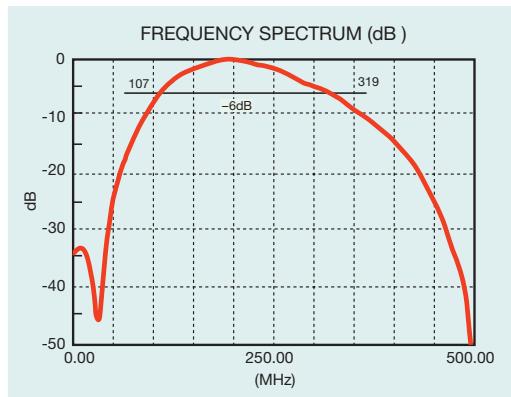

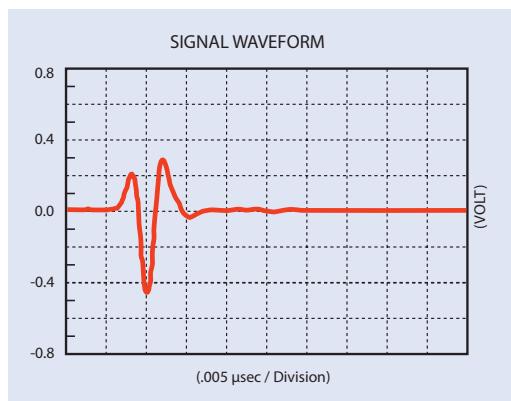

*Thickness range depends on material, transducer, surface condition, temperature, and setup selected.

High Frequency Contact

- Permanent fused silica delay line allows for flaw evaluation, material analysis, or thickness measurements using a direct contact testing method.
- Three different delay line configurations (BA, BB, BC) allow for various combinations of delay line echoes.
- Standard connector style is Right Angle Microdot (RM).

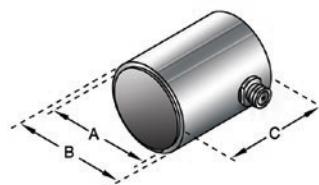

Frequency	Nominal Element Size		Delay	Transducer Part Numbers

Please contact us for transducers in higher frequencies.

Contact transducers are available in frequencies up to 225 MHz.

Performance is dependent on pulser/receiver and application. All transducers are manufactured on a special basis to customer specifications. Contact us to discuss applications.

Transducer Dimensions
(in inches)

Delay Style	(A)	(B)	(C)

BB	0.34	0.44	0.81
BC	0.34	0.44	0.63

High Frequency Standard Immersion Case

- Permanent fused silica delay line
- Focused units use an optical quality ground lens.
- F202 adaptor allows fixturing with a passive UHF connector and an active Microdot style connector (see "Coulants and Adaptors" on page 37).
- Combines high frequency with a small case design

V358-SU

High Frequency SU/RM Immersion Case

- Permanent fused silica delay with an optical quality ground lens provides a high degree of precision in beam alignment and focusing.
- Stainless steel case has a passive Straight UHF (SU) connector and an active Right Angle Microdot (RM) connector.
- Large cases allow for larger delay lines and decrease in delay reverberations and noise.

Polymer (PVDF) Immersion Transducers

- Provides optimal impedance match to water without the use of a delay line or lens.
- No delay line echoes as seen in fused silica designs.
- Broadband performance

Frequency	Nominal Element Size		Delay	Focal Length		Transducer Part Numbers

V3194 with F109 transformer

*Transducers create surface waves in steel, titanium and other materials with similar velocities. Please contact us for higher frequency. Lightweight High Frequency transducers are an alternative to the SU/RM case style transducers. They offer a smaller case width and lighter weight without sacrificing performance.

Frequency	Nominal Element Size	Part Number	Standard Focal Lengths		
			MHz	in.	in.
15	0.25	PI15-2-RX.XX"			1.00
20	0.25	PI20-2-RX.XX"			0.50, 1.00, 1.50, 2.00
35	0.25	PI35-2-RX.XX"			0.50, 0.75, 1.00, 1.50, 2.00
50	0.25	PI50-2-RX.XX"			0.50, 0.75, 1.00, 1.50, 2.00
75	0.125	PI75-1-RX.XX"			0.50, 1.00

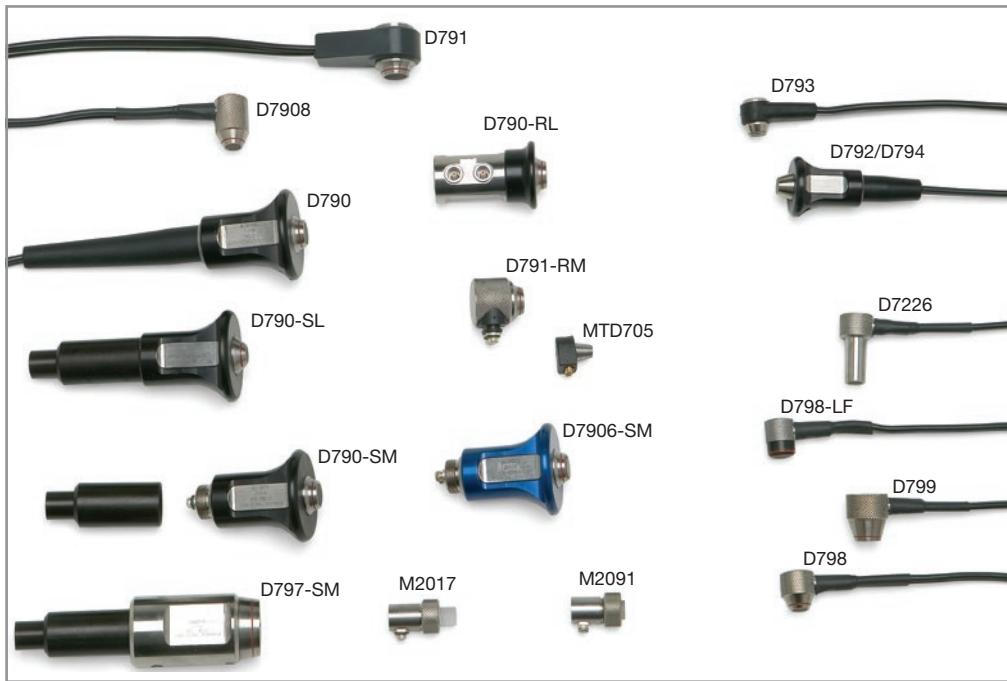

Note: Please replace X.XX" with the standard focal length of your choice.

Due to the fact that polymer transducers are inherently broadband, their center frequency may be lower than the frequency indicated on the transducer.

Note: Polymer transducer center frequencies are based on the film thickness of the polymer film element. Performance is highly dependent on pulser and cable characteristics and effective center frequency may be 15% to 25% lower than the nominal value.

Dual Element Transducers for Thickness Gages

Olympus NDT offers a complete line of dual element and single element transducers for use with its corrosion thickness gages. Most of these transducers feature Automatic Probe Recognition for maximum gage performance for each transducer. These transducers are available in an assortment of frequencies, sizes, and temperature capabilities to provide an off-the-shelf solution to most corrosion applications.

* Thru-Coat Transducers

† Adaptor required for E110 (part number 1/2XA/E110).

Electromagnetic Acoustic Transducer (EMAT)

Electromagnetic Acoustic Transducers are single element transducers that employ a magnetostrictive effect to transmit and receive ultrasonic waves. Part number E110-SB.

Advantages

- No need to remove external scale
- No couplant required
- Use in contact with or at a small distance from surface

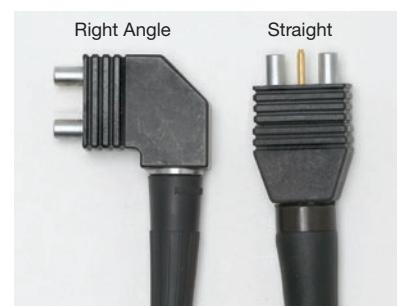

Applications

- External oxide scaled surfaces
- For use with 38DL Plus thickness gage and conventional UT flaw detectors

*Temperature specification are 32°F to 140°F (0°C to 60°C) for continuous contact and 176°F (80°C) for intermittent contact, defined as 10 seconds in contact with part and 60 seconds of cooling time. **Adaptor required. Please order separately. Part number 1/2XA/E110.

The above picture illustrates the Panametrics® RLCMD (Right Angle) and LCMD (Straight) probe recognition plugs that are compatible only with Panametrics brand thickness gages. The Probe Recognition technology automatically notifies the gage of the frequency and probe type being used. No information needs to be entered by the inspector.

Atlas European Standard Transducers

Our Altas European Standard transducers are available in Dual Element, Angle Beam, Contact, and Protected Face styles designed to meet inspection criteria referenced throughout Europe and the rest of the world. Our Altas transducers are available in metric unit element diameters and common frequencies, such as 1, 2, 4, 5, and 6 MHz.

TOFD Transducers

Our time-of-flight diffraction transducers are highly damped longitudinal wave probes that offer excellent resolution in challenging TOFD applications. These highly sensitive composite element broadband transducers are available in frequencies from 2.25 MHz to 15 MHz and in sizes from 3 mm (0.25 in.) to 12 mm (0.50 in.). They are for use with specialized TOFD wedges designed to produce refracted longitudinal waves in steel.

TOFD scan screen shot generated with Olympus OmniPC software.

TOFD Wedges Ordering Number Nomenclature

ST	1	-	45	L	-	IHC	-	A	OD	8

→ Diameter of Curvature, example: 8: 8 inches
 → OD: Outside Diameter
 → ID: Inside Diameter
 → Curvature direction
 → A: Axial C: Circumferential
 → IHC: Irrigation, scanner holes, and carbides
 → IHS*: Irrigation and scanner holes with Stainless Steel construction
 → L: Longitudinal Wave
 → Refracted angle in steel, examples: 45, 60, 70 deg
 → Probe casing model: 1,2

*Only available for ST1 models

Special Transducers

Low Frequency Narrowband Transducers

Meant for use in pairs for through transmission in materials such as concrete, wood, and geological samples, these are available in frequencies of 50 kHz (X1021), 100 kHz (X1020), and 180 kHz (X1019). Recommended instruments are high voltage pulser-receivers such as the Model 5058PR or 5077PR Square Wave Pulser.

500 kHz Broadband/Highly Damped Transducers

This highly damped transducer measures the thickness of fiberglass, composites, and other attenuating materials. This transducer can also be used with a NWC-302 Nylon Wear Cap for flaw detection on thick or rough surfaced casting materials.

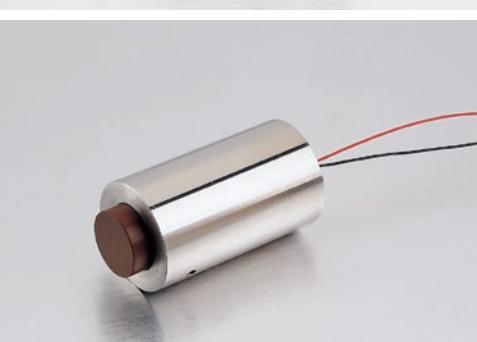

Part number is M2008, (1.5 in., 38 mm diameter).

Variable Angle Beam Wedge

The Variable Angle Beam Wedge allows the user to adjust the incident angle from 0° to 50° to create refracted angles in steel from 0° to 90°. The wedge is to be used with the 0.50 x 1.00 in. Standard Angle Beam Transducers (see "Standard Angle Beam Transducers" on page 14).

Wedge Part Number = ABWX-2001

Continuous High Temperature Delay Line Transducer

This transducer can continuously withstand temperatures as high as 350°F (175 °C) and pressures up to 85 PSIG. One typical application is to monitor the cure of materials in autoclave.

Part number is X2002, (2.25 MHz, 0.5 inch, 13 mm diameter).

Couplants and Adaptors

Couplants

The use of couplant is almost always necessary to provide acoustic coupling between the transducer and the test piece. We offer various types of couplants to suit virtually all applications.

Part Number	Description	Volume	Application
B2	Glycerin	2 oz. (0.06 liter)	General purpose, more viscous and has a high acoustic impedance making it the preferred couplant for rough surfaces and highly attenuating materials.
D12	Gel Type	12 oz. (0.35 liter)	Rough surfaces such as sand-cast metals and fiberglass layups, weld inspections, overhead surfaces or vertical walls.
G-4	Medium Temp	4 oz. (0.12 liter)	Temperature range 0°F to 600°F (-12°C to 315°C) Easy removal at high temperatures, non-toxic and biodegradable.
H-2	High Temp	2 oz. (0.06 liter)	Temperature range 0°F to 950°F (-18°C to 510°Ct) in many open environment applications when used per manufacturer's recommended procedure.*
SWC	Shear Wave	4 oz. (0.12 liter)	Normal incidence shear wave, non-toxic, water soluble organic substance of very high viscosity.

*Typical UT flaw and thickness applications use thin couplant films in an open environment where the small amount of gas formed can dissipate quickly. However, if an unlikely couplant gas auto ignition flash is of major concern, this couplant should not be used above the auto ignition temperature of 800°F (425°C).

Adaptors

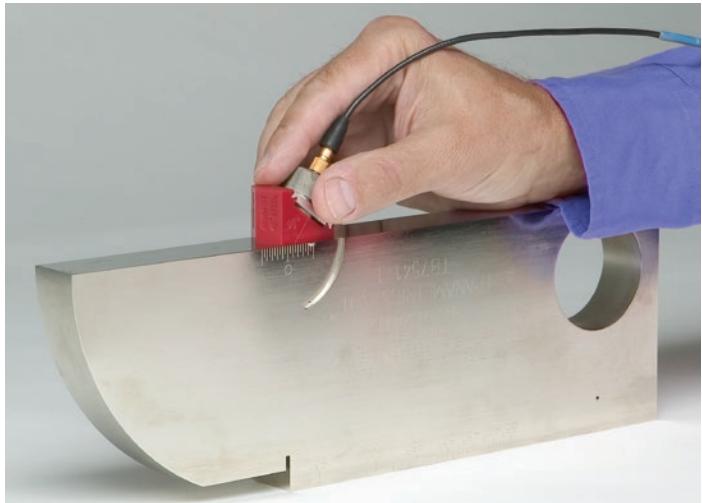

Part Numbers	Fits Connector Style
F108	Right Angle UHF Male to UHF Female, waterproof
F195	45° UHF Female to UHF Male
F202	Active UHF Female to Passive UHF Male/Active Right Angle Microdot Female
F206	UHF to Flange
F267	Right Angle UHF Female to UHF Male, waterproof
BF-BF	BNC Female to BNC Female
BM-BM	BNC Male to BNC Male
BM-UF	BNC Male to UHF Female
L1F-BM	LEMO 1 Female to BNC Male
L1M-BF	LEMO 1 Male to BNC Female
LM-BF	LEMO 00 Male to BNC Female
LF-BM	LEMO 00 Female to BNC Male
MM-UMW	Microdot Male to UHF Male, waterproof
UM-BF	UHF Male to BNC Female
LF-UM	LEMO 00 Female to UHF Male
MM-UFW	Microdot Male to UHF Female, waterproof

Test Blocks

Calibration and/or reference blocks should be used in every application. Standard blocks are available for angle beam calibrations and thickness calibrations of common materials.

- Blocks manufactured from 1018 steel, 304 stainless steel, or 7075-T6 aluminum are commonly in stock (other materials require special quotes for price and delivery).
- Contact us for more information regarding materials not listed, blocks not listed, or custom blocks.

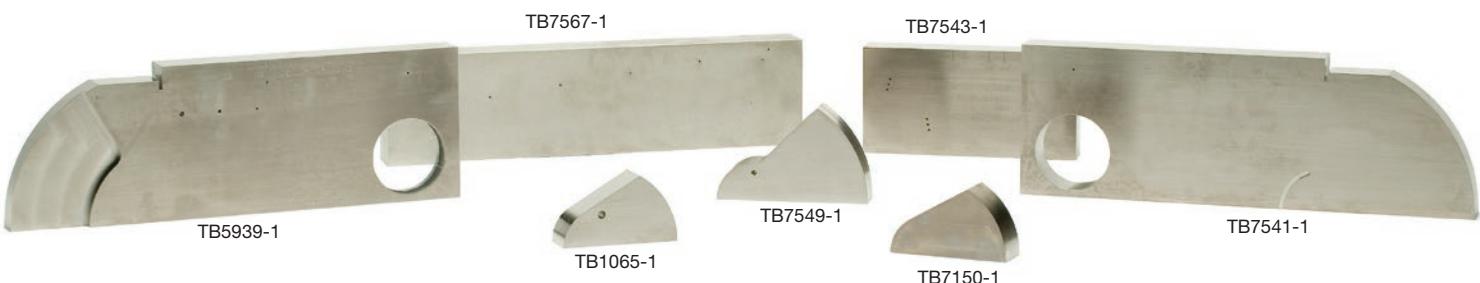

Calibration Blocks

All blocks are checked dimensionally using measuring equipment traceable to the National Institute of Standards and Technology, NIST. The most commonly required calibration blocks are listed below.

Type	Part Number	Description	Hardwood Case
ASTM E164 Calibration IIW-Type Block	TB7541-X	Meets AASHTO and AWS Type 1 block requirements. Calibrates distance and sensitivity settings. Measure refracted angle and sound exit point of angle beam transducers. U.S. customary units (inches).	F129
	TB1136-X	Meets AASHTO and AWS Type 1 block requirements. Calibrates distance and sensitivity settings. Measure refracted angle and sound exit point of angle beam transducers. U.S. customary units (inches). Block with Lucite plug.	F129
	TB1054-X	Metric units.	F129
	TB1137-X	Metric units. Block with Lucite plug.	F129
US Air Force IIW-2 Calibration Block	TB5939-X	IIW-type block per U.S. Air Force NDI Manual T.O. 33B -1-1. Includes 2 in. and 4 in. radius cutouts for distance calibration. No. 3, No. 5, and No. 8 side drilled holes, and distance calibration marks to the 2 in. hole.	F129
RC AWS Block	TB7543-X	Determining resolution capabilities of angle beam transducers per AWS and AASHTO requirements.	F157
SC AWS Block	TB7545-X	Sensitivity and refracted angle calibration per AWS and AASHTO requirements.	F158
DC AWS Block	TB7547-X	Distance and beam index calibration for angle beam transducers per AWS and AASHTO requirements.	F159
DSC AWS Block	TB7549-X	Distance, sensitivity, refracted angle and beam index calibration for angle beam transducers per AWS and AASHTO requirements.	F160
DS AWS Block	TB7551-X	Calibration block for horizontal linearity and dB accuracy procedures per AWS and AASHTO requirements.	F161
30FBH Resolution Reference Block	TB7160-X	Evaluate near surface resolution and flaw size/depth sensitivity of UT equipment. No. 3, No. 5, and No. 8 ASTM flat bottom holes at ten metal travel distances from 0.050 in. to 1.250 in.	Included
NAVSHIPS Block	TB7567-X	Contains six No. 3 side drilled holes. Used for distance-amplitude calibration per NAVSHIPS 0900-006 -3010.	F162
ASTM E164 MAB Block	TB7150-X	Miniature Angle Beam (ROMPAS) Block. Distance, beam index, refracted angle, and sensitivity calibration. One inch thick.	F197
ISO 7963 Steel	TB1065-X	Miniature Angle Beam Block Distance, beam index, refracted angle and sensitivity calibration. 25 mm thick.	F197

Replace the "X" in the part number with the appropriate number listed below to signify block material:

1 = 1018 Steel
2 = 4340 Steel
4 = 7075-T6 Aluminum
5 = 304 Stainless Steel
8 = 6-4 Titanium

Reference Blocks

We offer commonly used sets of reference blocks recommended by ASTM standards. These sets are manufactured to ASTM E127 and ASTM E428 physical dimensions requirements. All reference blocks are provided with an ultrasonic response curve. We can provide, by special order, materials not listed and individual reference blocks. Contact us for more information regarding materials not listed, custom calibration blocks, or quotations on blocks not listed in this section.

Distance-Amplitude Blocks

Type of Set*	Part Number	Description of Set					
Distance-Area Amplitude Set	TB6100-X	Set of 10 ASTM E 127 (7075 Alum) or ASTM E 428 (all other materials) basic set consisting of $\frac{3}{64}$ at 3 in., $\frac{5}{64}$ at $\frac{1}{8}$ in., $\frac{1}{4}$ in., $\frac{1}{2}$ in., $\frac{3}{4}$ in., 1- $\frac{1}{2}$ in., 3 in., and 6 in., and $\frac{6}{64}$ at 3 in. and 6 in. This set is used for determining dead zone, sensitivity, distance and area amplitude linearity measurement.					
Area-Amplitude Set	TB6200-X	Set of 8 ASTM E 127 (7075 Alum) or ASTM E 428 (all other materials) Area Amplitude Set consisting of $\frac{1}{64}$, $\frac{2}{64}$, $\frac{3}{64}$, $\frac{4}{64}$, $\frac{5}{64}$, $\frac{6}{64}$, $\frac{7}{64}$, and $\frac{8}{64}$ flat bottom holes at 3 in. This set is used to determine the relationship between flaw size and echo amplitude by comparing signal response.					
Distance-Amplitude Set-No. 3FBH	TB6303-X	Set of 19 ASTM E 127 (7075 Alum) or ASTM E 428 (all other materials) Distance Amplitude Set. All flat bottom holes are the same and metal travel distances are $\frac{1}{16}$ in., $\frac{1}{8}$ in., $\frac{1}{4}$ in., $\frac{3}{16}$ in., $\frac{1}{2}$ in., $\frac{5}{8}$ in., $\frac{3}{4}$ in., $\frac{7}{8}$ in., 1 in., 1- $\frac{1}{4}$ in., 1- $\frac{3}{4}$ in., 2- $\frac{1}{4}$ in., 2- $\frac{3}{4}$ in., 3- $\frac{1}{4}$ in., 3- $\frac{3}{4}$ in., 4 in., 4- $\frac{3}{4}$ in., 5- $\frac{1}{4}$ in., and 5- $\frac{3}{4}$ in. This set is used to determine the relationship between metal distance and signal amplitude by comparing signal responses obtained.					
Distance-Amplitude Set-No. 5FBH	TB6305-X	$\frac{1}{16}$ in.	$\frac{1}{2}$ in.	1 in.	2- $\frac{1}{4}$ in.	3- $\frac{1}{4}$ in.	4- $\frac{1}{4}$ in.
Distance-Amplitude Set-No. 8FBH	TB6308-X	$\frac{1}{8}$ in.	$\frac{5}{8}$ in.	1- $\frac{1}{4}$ in.	2- $\frac{3}{4}$ in.	3- $\frac{3}{4}$ in.	4- $\frac{3}{4}$ in.
Sensitivity-Resolution Set	TB6025-X	$\frac{1}{4}$ in.	$\frac{3}{4}$ in.	1- $\frac{3}{4}$ in.			
		$\frac{3}{8}$ in.	$\frac{7}{8}$ in.				
		Set of 9 ASTM E 127 (7075 Alum) or ASTM E 428 (all other materials) consisting of $\frac{1}{64}$ at 3 in., $\frac{2}{64}$ at 3 in., and $\frac{5}{64}$ at $\frac{1}{8}$ in., $\frac{1}{4}$ in., $\frac{3}{8}$ in., $\frac{1}{2}$ in., $\frac{3}{4}$ in., 1 in., and 1- $\frac{1}{2}$ in., and 1 ASTM E 317 horizontal and vertical linearity block used to evaluate the sensitivity, entry surface resolution, and horizontal and vertical linearity characteristics of UT equipment.					

Replace the "X" in the part number with the appropriate number listed below to signify block material:

1 = 1018 Steel

2 = 4340 Steel

4 = 7075-T6 Aluminum

5 = 304 Stainless Steel

8 = 6-4 Titanium

*Includes Hardwood case

Thickness Calibration Blocks

- Blocks are held to tighter tolerances than called out in ASTM E797 Code.

Material	Part Numbers	Steps
304 Stainless Steel	2211E	0.100 in., 0.200 in., 0.300 in., 0.400 in., 0.500 in.
304 Stainless Steel	2211M	2.5 mm, 5.0 mm, 7.5 mm, 10.0 mm, 12.5 mm
1018 Carbon Steel	2212E	0.250 in., 0.500 in., 0.750 in., 1.00 in.
1018 Carbon Steel	2212M	6.25 mm, 12.5 mm, 18.75 mm, 25 mm
7075-T6 Aluminum	2213E	0.100 in., 0.200 in., 0.300 in., 0.400 in., 0.500 in.
7075-T6 Aluminum	2213M	2.5 mm, 5.0 mm, 7.5 mm, 10.0 mm, 12.5 mm
1018 Carbon Steel	2214E	0.100 in., 0.200 in., 0.300 in., 0.400 in., 0.500 in.
1018 Carbon Steel	2214M	2.5 mm, 5.0 mm, 7.5 mm, 10.0 mm, 12.5 mm

Note: For hardwood case, order 2214C.

2214E

Cables

- Select from a variety of cable grades to meet your specific application needs.
- Standard lengths 3 ft (1 m), 4 ft (1.2 m), 6 ft (1.8 m). When ordering, replace the x in the part number with the desired cable length in feet.
- Custom cable lengths are available; please specify when ordering.
- Part numbering prefix indicates connector style for both ends of the cable.
- All cables are 50 ohms impedance unless otherwise specified.
- Contact us for special or customized cables.

Standard

Cable Part Numbers	Fits Connector Style
BCB-58-X	Fits BNC to BNC
BCB-74-X	Fits BNC to BNC
BCM-74-X	Fits BNC & Microdot
BCMA-74-X	Fits BNC & Microdot without Boot
BCRM-74-X	Fits BNC & Right Angle Microdot
BCU-58-X	Fits BNC to UHF
BCU-62-X	Fits BNC to UHF
FLCB-74-X	Fits Female LEMO & BNC
LCB-74-X	Fits Small LEMO 00 & BNC
LCM-74-X	Fits Small LEMO 00 & Microdot
LCU-74-X	Fits Small LEMO 00 & UHF
L1CB-58-X	Fits Large LEMO 1 & BNC
L1CM-74-X	Fits Large LEMO 1 & Microdot
L1CU-74-X	Fits Large LEMO 1 & UHF
L1CU-74-X	Fits Large LEMO 1 & UHF
UCM-74-X	Fits UHF and Microdot
UCU-58-X	Fits UHF to UHF

Heavy Duty (HD)

- External Teflon coating provides flexibility and improved cable performance in industrial settings

Cable Part Numbers	Fits Connector Style
BCB-188-X HD	Fits BNC to BNC
BCM-188-X HD	Fits BNC and Microdot
BCU-188-X HD	Fits BNC to UHF
LCB-188-X HD	Fits Small LEMO 00 and BNC
LCM-188-X HD	Fits Small LEMO 00 and Microdot

Waterproof (W)

- Specially designed proprietary waterproof UHF connector provides a waterproof connection good to depths of about 150 ft (50 m) in fresh water.

Cable Part Numbers	Fits Connector Style
BCM-74-X W	Fits BNC to Waterproof Microdot
BCRM-74-X W	Fits BNC to Waterproof Right Angle Microdot
BCU-58-X W	Fits BNC to Waterproof UHF
BCU-62-X W	Fits BNC to Waterproof UHF
BCU-74-X W	Fits BNC to Waterproof UHF
LCM-74-X W	Fits Small LEMO 00 to Waterproof Microdot
LCU-74-X W	Fits Small LEMO 00 to Waterproof UHF
L1CU-74-X W	Fits Large LEMO 1 to Waterproof UHF

Armored Stainless Steel (SSA)

Interlocking stainless steel jacket provides flexibility, protection, and ruggedness in heavy industrial settings

- Can be ordered in lengths up to 20 ft (6.1m)

Cable Part Numbers	Fits Connector Style
BCB-188-X SSA	Fits BNC to BNC
BCM-188-X SSA	Fits BNC and Microdot
BCRM-188-X SSA	Fits BNC and Right Angle Microdot
BCU-188-X SSA	Fits BNC to UHF
LCM-188-X SSA	Fits Small LEMO 00 and Microdot
LCRM-188-X SSA	Fits Small LEMO 00 and Right Angle Microdot

Double Shielded (DS)

- Additional grounded shield provides low cable noise for better performance in high frequency applications.
- 15 ohm or 25 ohm cable of different lengths may help to optimize high frequency system performance.

Cable Part Numbers	Fits Connector Style	Impedance
BCM-74-X DS	Fits BNC and Microdot	50 ohms
BCM-15-X DS	Fits BNC and Microdot	15 ohms
BCM-25-X DS	Fits BNC and Microdot	25 ohms

Cables with Handle

- Special 3 in. (75 mm) long reinforced handle for increased durability and easier grip
- Custom handles can be ordered 6 in. (152 mm) and 9 in. (229 mm)

Cable Part Numbers	Fits Connector Style	Handle Length
		inches
BCMH-74-X	Fits BNC and Microdot	3
LCMH-74-X	Fits Small LEMO 00 and Microdot	3
L1CMH-74-X	Fits Large LEMO 1 and Microdot	3
BCMH6-74-X	Fits BNC and Microdot	6
LCMH6-74-X	Fits Small LEMO 00 and Microdot	6
L1CMH6-74-X	Fits Large LEMO 1 and Microdot	6
BCMH9-74-X	Fits BNC and Microdot	9
LCMH9-74-X	Fits Small LEMO 00 and Microdot	9
L1CMH9-74-X	Fits Large LEMO 1 and Microdot	9

Technical Notes

The Technical Notes section is designed to provide a brief overview of the ultrasonic principles important to transducer application and design. The Technical Notes are organized in the following sections:

1. Basic ultrasonic principles
2. Advanced definitions and formulas
3. Design characteristics of transducers
4. Transducer specific principles
5. Transducer excitation guidelines
6. Cables

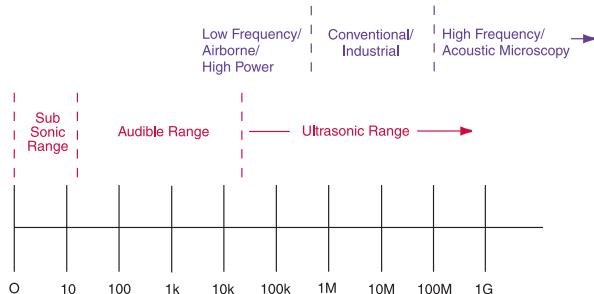

1. Basic Ultrasonic Principles

a. What is Ultrasound?

Sound generated above the human hearing range (typically 20 kHz) is called ultrasound. However, the frequency range normally employed in ultrasonic nondestructive testing and thickness gaging is 100 kHz to 50 MHz. Although ultrasound behaves in a similar manner to audible sound, it has a much shorter wavelength. This means it can be reflected off very small surfaces such as defects inside materials. It is this property that makes ultrasound useful for nondestructive testing of materials.

The Acoustic Spectrum in Figure (1) breaks down sound into three ranges of frequencies. The Ultrasonic Range is then broken down further into three sub-sections.

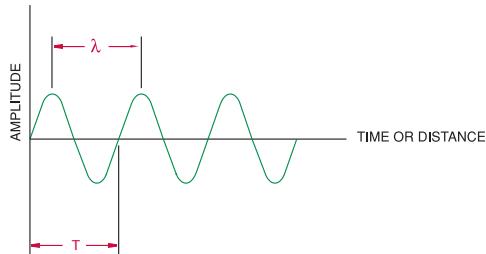

Fig. 1

b. Frequency, Period and Wavelength

Ultrasonic vibrations travel in the form of a wave, similar to the way light travels. However, unlike light waves, which can travel in a vacuum (empty space), ultrasound requires an elastic medium such as a liquid or a solid. Shown in Figure (2) are the basic parameters of a continuous wave (cw). These parameters include the wavelength (λ) and the period (T) of a complete cycle.

Fig. 2

The number of cycles completed in one second is called frequency (f) and is measured in hertz (Hz), with multiples as follows;

- 1 cycle/second = 1 Hz
- 1000 cycles/second = 1 kHz
- 1,000,000 cycles/second = 1 MHz

The time required to complete a full cycle is the period (T), measured in seconds. The relation between frequency and period in a continuous wave is given in Equation (1).

Eqn. 1

$$f = 1/T$$

c. Velocity of Ultrasound and Wavelength

The velocity of ultrasound (c) in a perfectly elastic material at a given temperature and pressure is constant. The relation between c , f , λ and T is given by Equations (2) and (3):

Eqn. 2

$$\lambda = c/f$$

Eqn. 3

$$\lambda = cT$$

λ = Wavelength
 c = Material Sound Velocity
 f = Frequency
 T = Period of time

"Table 2 - Acoustic Properties of Materials" on page 52 lists the longitudinal and shear wave velocities of materials that are commonly tested with ultrasonics.

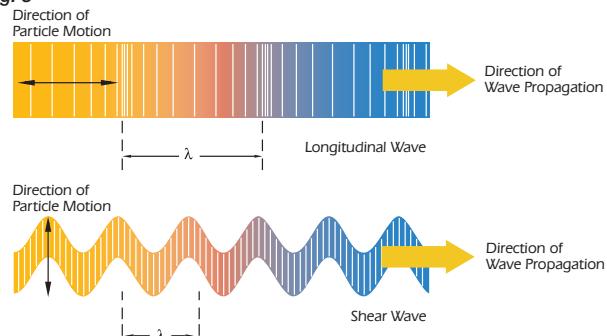

d. Wave Propagation and Particle Motion

The most common methods of ultrasonic examination utilize either longitudinal waves or shear waves. Other forms of sound propagation exist, including surface waves and Lamb waves.

- A longitudinal wave is a compressional wave in which the particle motion is in the same direction as the propagation of the wave.
- A shear wave is a wave motion in which the particle motion is perpendicular to the direction of the propagation.
- Surface (Rayleigh) waves have an elliptical particle motion and travel across the surface of a material. Their velocity is approximately 90% of the shear wave velocity of the material and their depth of penetration is approximately equal to one wavelength.
- Plate (Lamb) waves have a complex vibration occurring in materials where thickness is less than the wavelength of ultrasound introduced into it.

Figure (3) provides an illustration of the particle motion versus the direction of wave propagation for longitudinal waves and shear waves.

Fig. 3

Technical Notes

e. Applying Ultrasound

Ultrasonic nondestructive testing introduces high frequency sound waves into a test object to obtain information about the object without altering or damaging it in any way. Two basic quantities are measured in ultrasonic testing; they are time of flight or the amount of time for the sound to travel through the sample, and the amplitude of the received signal. Based on velocity and round trip time of flight through the material the material, thickness can be calculated as follows:

Eqn. 4

$$T = \frac{ct}{2}$$

T = Material Thickness
c = Material Sound Velocity
t = Time of Flight

Measurements of the relative change in signal amplitude can be used in sizing flaws or measuring the attenuation of a material. The relative change in signal amplitude is commonly measured in decibels. Decibel values are the logarithmic value of the ratio of two signal amplitudes. This can be calculated using the following equation. Some useful relationships are also displayed in the table below;

Eqn. 5

$$dB = 20 \log_{10} (A_1/A_2)$$

dB = Decibels
A₁ = Amplitude of signal 1
A₂ = Amplitude of signal 2

A ₁	Ratio	dB
A ₂		
100%	1.4142	3
70.71%		
100%	2	6
50%		
100%	4	12
25%		
100%	10	20
10%		
100%	100	40
1%		

f. Sensitivity and Resolution

- Sensitivity is the ability of an ultrasonic system to detect reflectors (or defects) at a given depth in a test material. The greater the signal that is received from a given reflector, the more sensitive the transducer system.
- Axial resolution is the ability of an ultrasonic system to produce simultaneous and distinct indications from reflectors located at nearly the same position with respect to the sound beam.
- Near surface resolution is the ability of the ultrasonic system to detect reflectors located close to the surface of the test piece.

2. Advanced Definitions And Formulas

a. Transducer Waveform and Spectrum

Transducer waveform and spectrum analysis is done according to test conditions and definitions of ASTM E1065. Typical units are MHz for frequency analysis, microseconds for waveform analysis, and dB down from peak amplitude. Figure (4) illustrates waveform duration at the -14 dB level or 20% amplitude of peak. The -40 dB waveform duration corresponds to 1% amplitude of peak.

Fig. 4

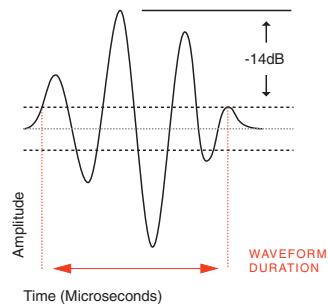

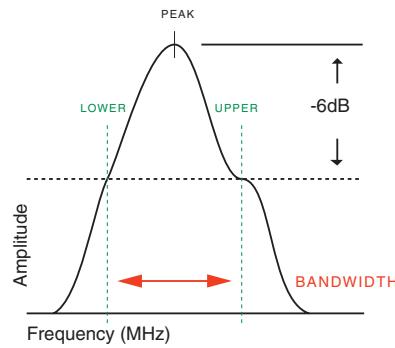

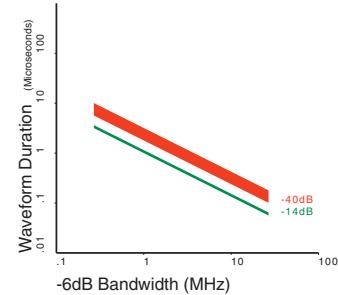

Figure (5) illustrates peak frequency, upper and lower -6 dB frequencies and MHz bandwidth measurements.

Fig. 5

The relation between MHz bandwidth and waveform duration is shown in Figure (6). The scatter is wider at -40 dB because the 1% trailing end of the waveform contains very little energy and so has very little effect on the analysis of bandwidth. Because of the scatter it is most appropriate to specify waveforms in the time domain (microseconds) and spectra in the frequency domain.

Fig. 6

The approximate relations shown in Figure (6) can be used to assist in transducer selection. For example, if a -14 dB waveform duration of one microsecond is needed, what frequency transducer should be selected? From the graph, a bandwidth of approximately 1 to 1.2 MHz corresponds to approximately 1 microsecond -14 dB waveform duration. Assuming a nominal 50% fractional bandwidth transducer, this calculates to a nominal center frequency of 2 to 2.4 MHz. Therefore, a transducer of 2.25 MHz or 3.5 MHz may be applicable.

b. Acoustic Impedance, Reflectivity and Attenuation

The acoustic impedance of a material is the opposition to displacement of its particles by sound and occurs in many equations. Acoustic impedance is calculated as follows:

Eqn. 6

$$Z = pc$$

Z	=	Acoustic Impedance
c	=	Material Sound Velocity
p	=	Material Density

The boundary between two materials of different acoustic impedances is called an acoustic interface. When sound strikes an acoustic interface at normal incidence, some amount of sound energy is reflected and some amount is transmitted across the boundary. The dB loss of energy on transmitting a signal from medium 1 into medium 2 is given by:

Eqn. 7a

$$\text{dB loss} = 10 \log_{10} [4Z_1 Z_2 / (Z_1 + Z_2)^2]$$

Z_1	=	Acoustic Impedance of First Material
Z_2	=	Acoustic Impedance of Second Material

The dB loss of energy of the echo signal in medium 1 reflecting from an interface boundary with medium 2 is given by:

Eqn. 7b

$$\text{dB loss} = 10 \log_{10} [(Z_2 - Z_1)^2 / (Z_1 + Z_2)^2]$$

For example: The dB loss on transmitting from water ($Z = 1.48$) into 1020 steel ($Z = 45.41$) is -9.13 dB; this also is the loss transmitting from 1020 steel into water. The dB loss of the backwall echo in 1020 steel in water is -0.57 dB; this also is the dB loss of the echo off 1020 steel in water. The waveform of the echo is inverted when $Z_2 < Z_1$.

Finally, ultrasound attenuates as it progresses through a medium. Assuming no major reflections, there are three causes of attenuation: diffraction, scattering and absorption. The amount of attenuation through a material can play an important role in the selection of a transducer for an application.

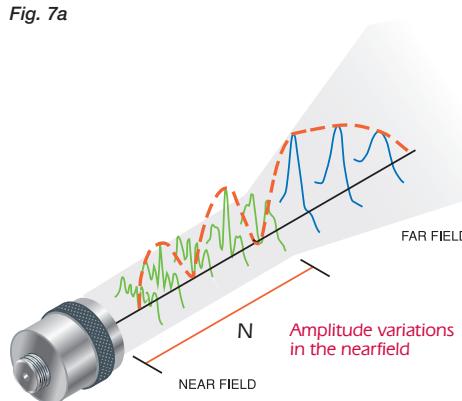

c. Sound Field

The sound field of a transducer is divided into two zones (figure 7a); the near field and the far field. The near field is the region directly in front of the transducer where the echo amplitude goes through a series of maxima and minima and ends at the last maximum, at distance N from the transducer. In the beam profile below, figure 7, red represents areas of highest energy, while green and blue represent lower energy.

Fig. 7

Fig. 7a

The location of the last maximum is known as the near field distance (N or Y_0^+) and is the natural focus of the transducer. The far field is the area beyond N where the sound field pressure gradually drops to zero. Because of the variations within the near field it can be difficult to accurately evaluate flaws using amplitude based techniques. The near field distance is a function of the transducer frequency, element diameter, and the sound velocity of the test material as shown by Equation 8:

Eqn. 8

$$N = D^2 f / 4c$$

Eqn. 8a

$$N = D^2 / 4\lambda$$

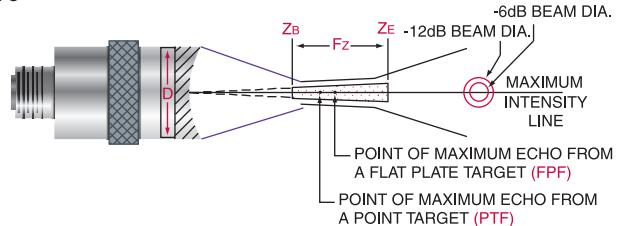

N	=	Near Field Distance
D	=	Element Diameter
f	=	Frequency
c	=	Material Sound Velocity
λ	=	Wavelength

("Table 1 - Near Field Distance of Flat Transducers in Water" on page 51 lists the near field distances in water for many combinations of transducer frequency and element diameter.)

d. Other Parameters of a Sound Beam

There are a number of sound field parameters that are useful in describing the characteristics of a transducer. In addition to the near field, knowledge of the beam width and focal zone may be necessary in order to determine whether a particular transducer is appropriate for a given inspection. Figure 8 gives a graphical representation of these parameters:

Fig. 8

Z_B = Beginning of the Focal Zone

F_Z = Focal Zone

Z_E = End of the Focal Zone

D = Element Diameter

Note that the distance to the maximum echo from a flat plate target and the maximum echo from a point target are not the same, although both will occur within the calculated -6 dB focal zone.

Technical Notes

Beam Diameter

A transducer's sensitivity is affected by the beam diameter at the point of interest. The smaller the beam diameter, the greater the amount of energy is reflected by a flaw. The -6 dB pulse-echo beam diameter at the focus can be calculated with Equation 9 or 9a. For a flat transducer use Equation 9a with $S_F = 1$

Eqn. 9

$$BD(-6 \text{ dB}) = 1.02Fc/fD$$

Eqn. 9a

$$BD(-6 \text{ dB}) = .2568DS_F$$

BD	= Beam Diameter
F	= Focal Length
c	= Material Sound Velocity
f	= Frequency
D	= Element Diameter
S_F	= Normalized Focal Length (Eqn. 14)

Focal Zone

The starting and ending points of the focal zone are located where the on-axis pulse-echo signal amplitude drops to -6 dB of the amplitude at the focal point. The length of the focal zone is given by Equation 10:

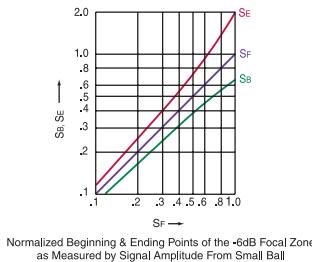

Eqn. 10

$$F_Z = N * S_F^2 [2/(1 + .5S_F)]$$

F_Z	= Focal Zone
N	= Near Field
S_F	= Normalized Focal Length (Eqn. 14)

Figure (9) shows the normalized beginning (S_B) and ending (S_E) point of the -6 dB focal zone versus the focusing factor.

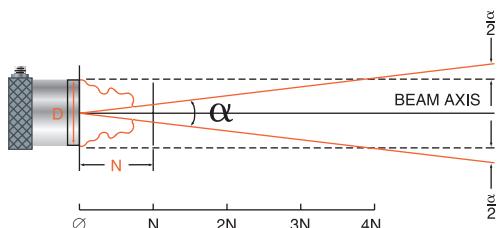

Fig. 9
-6 dB Focal Zone

Beam Spread and Half Angle

All ultrasonic beams diverge. In other words, all transducers have beam spread. Figure (10) gives a simplified view of a sound beam for a flat transducer. In the near field, the beam has a complex shape that narrows. In the far field the beam diverges.

Fig. 10

For flat transducers as shown in Figure (10), the -6 dB pulse-echo beam

spread angle is given by Equation (11):

Eqn. 11

$$\sin(\alpha/2) = .514c/fD$$

$\alpha/2$ = Half Angle Spread between -6 dB points

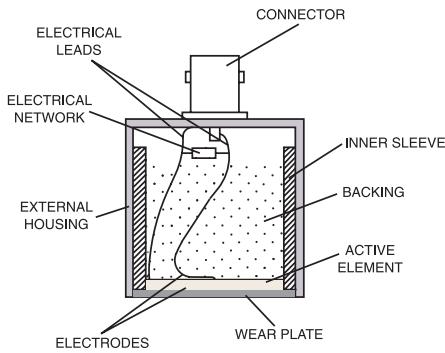

It can be seen from this equation that beam spread from a transducer can be reduced by selecting a transducer with a higher frequency or a larger element diameter or both.

3. Design Characteristics Of Transducers

a. What is an Ultrasonic Transducer?

A transducer is any device that converts one form of energy to another. An ultrasonic transducer converts electrical energy to mechanical energy, in the form of sound, and vice versa. The main components are the active element, backing, and wear plate.

Fig. 11

b. The Active Element

The active element, which is piezo or ferroelectric material, converts electrical energy such as an excitation pulse from a flaw detector into ultrasonic energy. The most commonly used materials are polarized ceramics which can be cut in a variety of manners to produce different wave modes. New materials such as piezo polymers and composites are also being employed for applications where they provide benefit to transducer and system performance.

c. Backing

The backing is usually a highly attenuative, high density material that is used to control the vibration of the transducer by absorbing the energy radiating from the back face of the active element. When the acoustic impedance of the backing matches the acoustic impedance of the active element, the result will be a heavily damped transducer that displays good range resolution but may be lower in signal amplitude. If there is a mismatch in acoustic impedance between the element and the backing, more sound energy will be reflected forward into the test material. The end result is a transducer that is lower in resolution due to a longer waveform duration, but may be higher in signal amplitude or greater in sensitivity.

d. Wear Plate

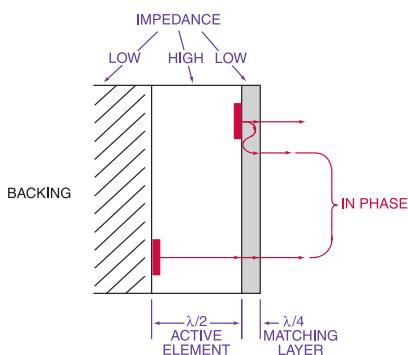

The basic purpose of the transducer wear plate is to protect the transducer element from the testing environment. In the case of contact transducers, the wear plate must be a durable and corrosion resistant material in order to withstand the wear caused by use on materials such as steel.

For immersion, angle beam, and delay line transducers the wear plate has the additional purpose of serving as an acoustic transformer or matching

layer between the high acoustic impedance of the active element and the water, the wedge or the delay line, all of which are of lower acoustic impedance. This is accomplished by selecting a matching layer that is $\frac{1}{4}$ wavelength thick ($\lambda/4$) and of the desired acoustic impedance (the active element is nominally $\frac{1}{2}$ wavelength). The choice of the wear surface thickness is based upon the idea of superposition that allows waves generated by the active element to be in phase with the wave reverberating in the matching layer as shown in Figure (4).

When signals are in phase, their amplitudes are additive, thus a greater amplitude wave enters the test piece. Figure (12) shows the active element and the wear plate, and when they are in phase. If a transducer is not tightly controlled or designed with care and the proper materials, and the sound waves are not in phase, it causes a disruption in the wavefront.

Fig. 12

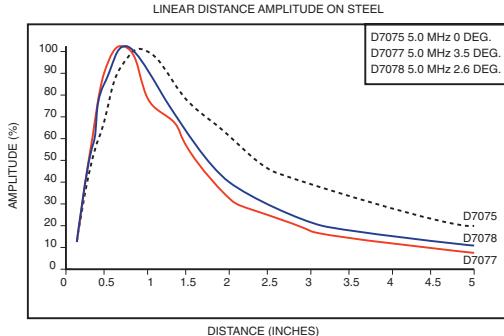

4. Transducer Specific Principles

a. Dual Element Transducers

Dual element transducers utilize separate transmitting and receiving elements, mounted on delay lines that are usually cut at an angle (see illustration on page 10). This configuration improves near surface resolution by eliminating main bang recovery problems. In addition, the crossed beam design provides a pseudo focus that makes duals more sensitive to echoes from irregular reflectors such as corrosion and pitting.

One consequence of the dual element design is a sharply defined distance/amplitude curve. In general, a decrease in the roof angle or an increase in the transducer element size will result in a longer pseudo-focal distance and an increase in useful range, as shown in Figure (13).

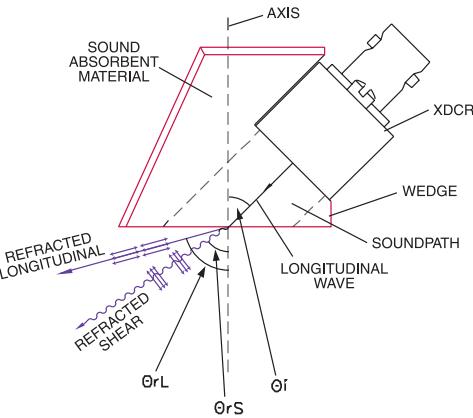

Fig. 13

b. Angle Beam Transducers

Angle beam transducers use the principles of refraction and mode conversion to produce refracted shear or longitudinal waves in the test material as shown in Figure (14).

Fig. 14

The incident angle necessary to produce a desired refracted wave (i.e. a 45° shear wave in steel) can be calculated from Snell's Law as shown in Equation (12). Because of the effects of beam spread, this equation doesn't hold at low frequency and small active element size. Contact us for details concerning these phenomena.

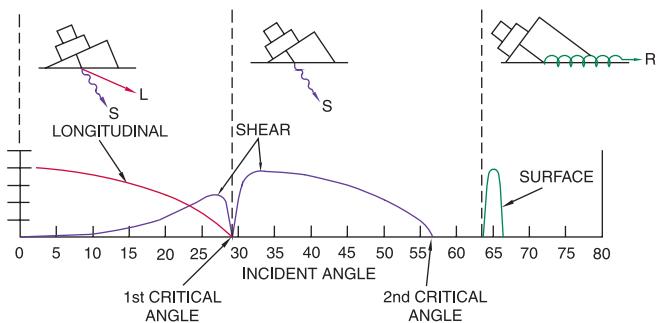

Eqn. 12

$$\sin\theta_i/c_i = \sin\theta_{rl}/c_{rl} = \sin\theta_{rs}/c_{rs}$$

θ_i	= Incident Angle of the Wedge
θ_{rl}	= Angle of the Refracted Longitudinal Wave
θ_{rs}	= Angle of the Refracted Shear Wave
c_i	= Velocity of the Incident Material (Longitudinal)
c_{rl}	= Material Sound Velocity (Longitudinal)
c_{rs}	= Velocity of the Test Material (Shear)

Figure (15) shows the relationship between the incident angle and the relative amplitudes of the refracted or mode converted longitudinal, shear, and surface waves that can be produced from a plastic wedge into steel.

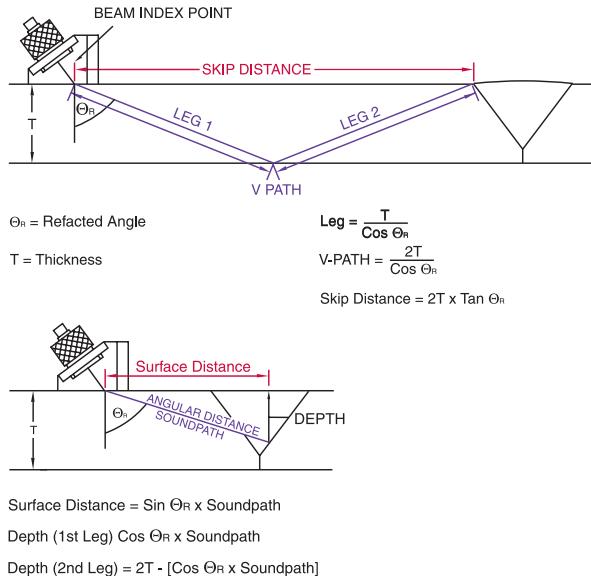

Fig. 15

Angle beam transducers are typically used to locate and/or size flaws which are oriented non-parallel to the test surface. Following are some of the common terms and formulas used to determine the location of a flaw.

Technical Notes

Fig. 16

Many AWS inspections are performed using refracted shear waves. However, grainy materials such as austenitic stainless steel may require refracted longitudinal waves or other angle beam techniques for successful inspections.

c. Delay Line Transducers

Delay line transducers are single element longitudinal wave transducers used in conjunction with a replaceable delay line.

One of the reasons for choosing a delay line transducer is that near surface resolution can be improved. The delay allows the element to stop vibrating before a return signal from the reflector can be received. When using a delay line transducer, there will be multiple echoes from end of the delay line and it is important to take these into account.

Another use of delay line transducers is in applications in which the test material is at an elevated temperature. The high temperature delay line options listed in this catalog (see "Delay Line Transducers" starting on page 18) are not intended for continuous contact, they are meant for intermittent contact only.

d. Immersion Transducers

Immersion transducers offer three major advantages over contact transducers:

- Uniform coupling reduces sensitivity variations.
- Reduction in scan time due to automated scanning.
- Focusing of immersion transducers increases sensitivity to small reflectors.

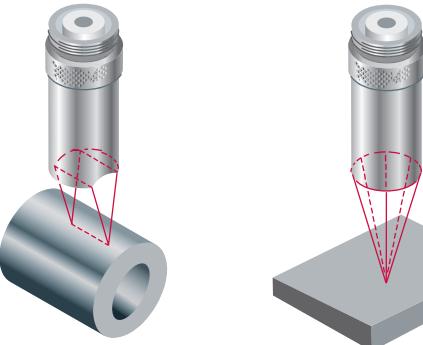

Focusing Configurations

Immersion transducers are available in three different configurations: unfocused ("flat"), spherically ("spot") focused, and cylindrically ("line") focused. Focusing is accomplished by either the addition of a lens or by curving the element itself. The addition of a lens is the most common way to focus a transducer.

An unfocused transducer may be used in general applications or for penetration of thick materials. A spherically focused transducer is commonly used to improve sensitivity to small flaws and a cylindrical focus is typically used in the inspection of tubing or bar stock. Examples of spherical and cylindrical focusing are shown in Figure (17).

Fig. 17

Cylindrical	Spherical

By definition, the focal length of a transducer is the distance from the face of the transducer to the point in the sound field where the signal with the maximum amplitude is located. In an unfocused transducer, this occurs at a distance from the face of the transducer which is approximately equivalent to the transducer's near field length. Because the last signal maximum occurs at a distance equivalent to the near field, a transducer, by definition, can not be acoustically focused at a distance greater than its near field.

Focus may be designated in three ways:

FPF (Flat Plate Focus) - For an FPF focus, the lens is designed to produce a maximum pulse/echo response from a flat plate target at the distance indicated by the focal length

PTF (Point Target Focus) - For a PTF focus, the lens is designed to produce a maximum pulse/echo response from a small ball target at the distance indicated by the focal length

OLF (Optical Limit Focus) - The OLF designation indicates that the lens is designed according to the lens maker's formula from physical optics and without reference to any operational definition of focal length. The OLF designation describes the lens and ignores diffraction effects.

When focusing a transducer, the type of focus (spherical or cylindrical), focal length, and the focal target (point or flat surface) need to be specified. Based on this information, the radius of curvature of the lens for the transducer which varies based on above parameters, can be calculated. When tested, the measured focal length will be off of the target specified.

There are limitations on focal lengths for transducers of a given frequency and element diameter for a particular focal designation. The maximum practical focal length for a flat plate focus (FPF) is 0.6 times the near field length, and for a point target focus (PTF) the maximum practical focal length is 0.8 times the near field length. Optical limit focus (OLF) focal length is not specifically constrained, but it should be understood that the actual maximum response point from a given target may not correspond to the distance indicated by the OLF focal length.

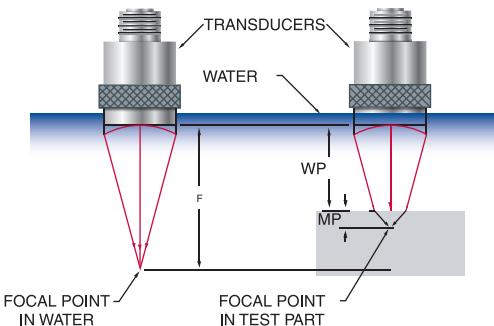

FPF and PTF transducers with focal lengths beyond these maximums, but less than the near field length, will usually be weakly focused units with only a small increase in sensitivity at the focal point. As a practical matter, there may be no functional advantage to a weakly focused transducer over a flat, unfocused transducer. In addition to acoustic limitations on maximum focal lengths, there are mechanical limitations on minimum focal lengths. Consult us for detailed information on focusing parameters.

"Table 1 - Near Field Distance of Flat Transducers in Water" on page 51 lists the near field distances as well as the minimum and maximum practical focal lengths for common frequency-element diameter combinations. Consult us for detailed information in focusing parameters.

Focal Length Variations due to Acoustic Velocity and Geometry of the Test Part

The measured focal length of a transducer is dependent on the material in which it is being measured. This is due to the fact that different materials have different sound velocities. When specifying a transducer's focal length it is typically specified for water. Since most materials have a higher velocity than water, the focal length is effectively shortened. This effect is caused by refraction (according to Snell's Law) and is illustrated in Figure (18).

Fig. 18

This change in the focal length can be predicted by Equation (13).

For example, given a particular focal length and material path, this equation can be used to determine the appropriate water path to compensate for the focusing effect in the test material.

Eqn. 13

$$WP = F - MP \left(\frac{c_{tm}}{c_w} \right)$$

WP	=	Water Path
MP	=	Material Depth
F	=	Focal Length in Water
c_{tm}	=	Sound Velocity in the Test Material
c_w	=	Sound Velocity in Water

In addition, the curvature of surface of the test piece can affect focusing. Depending on whether the entry surface is concave or convex, the sound beam may converge more rapidly than it would in a flat sample or it may spread and actually defocus.

Focusing Gain

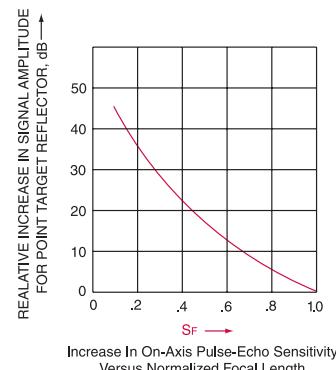

Focused immersion transducers use an acoustic lens to effectively shift the location of the Y_0^+ point toward the transducer face. The end result can be a dramatic increase in sensitivity. Figure (19) illustrates the relative increase in signal amplitude from small defects due to focusing where S_F is the normalized focal length and is given by Equation (14). The amplitude from a small defect cannot exceed the echo amplitude from a flat plate.

Eqn. 14

$$S_F = F/N$$

S_F	=	Normalized Focal Length
F	=	Focal Length
N	=	Near Field

Fig. 19

For example, the chart can be used to determine the increase in on-axis pulse-echo sensitivity of a 2.25 MHz, 1.0 in. element diameter transducer that is focused at 4 inches. The near field length of this transducer is 9.55 in., and the normalized focal length is 0.42 (4.0 in./9.55 in.). From the chart it can be seen that this will result in an increase in sensitivity of approximately 21 dB.

Focusing gain (dB) for cylindrical focuses can be estimated as being $\frac{3}{4}$ of the gain for spherical focuses.

e. Normal Incidence Shear Wave Transducers

Normal Incidence Shear Wave transducers incorporate a shear wave crystal in a contact transducer case. Rather than using the principles of refraction, as with the angle beam transducers, to produce shear waves in a material, the crystal itself produces the shear wave.

Typically these transducers are used to make shear velocity measurements of materials. This measurement, along with a longitudinal velocity measurement can be used in the calculation of Poisson's Ratio, Young's Modulus, and Shear Modulus. These formulas are listed below for reference.

Eqn. 15

$$\sigma = \frac{1-2(V_T/V_L)^2}{2+2(V_T/V_L)^2}$$

Eqn. 16

$$E = \frac{V_L^2 \rho (1 + \sigma)(1 - 2\sigma)}{(1 - \sigma)}$$

Eqn. 17

$$G = V_T^2 \rho$$

σ	=	Poisson's Ratio
V_L	=	Longitudinal Velocity
V_T	=	Shear (Transverse) Velocity
ρ	=	Material Density
E	=	Young's Modulus
G	=	Shear Modulus

Because shear waves do not propagate in liquids, it is necessary to use a very viscous couplant when making measurements with these. When using this type of transducer in a through transmission mode application, it is important that direction of polarity of each of the transducers is in line with the other. If the polarities are 90° off, the receiver may not receive the signal from the transmitter.

Technical Notes

5. Transducer Excitation Guidelines

As a general rule, all of our ultrasonic transducers are designed for negative spike excitation. The maximum spike excitation voltages should be limited to approximately 50 volts per mil of piezoelectric transducer thickness. Low frequency elements are thick, and high frequency elements are thin. A negative-going 600 volt fast rise time, short duration, spike excitation can be used across the terminals on transducers 5.0 MHz and lower in frequency. For 10 MHz transducers, the voltage used across the terminals should be halved to about 300 V as measured across the terminals.

Although negative spike excitation is recommended, continuous wave or tone burst excitations may be used. However there are limitations to consider when using these types of excitation. First, the average power dissipation to the transducer should not exceed 125 mW to avoid overheating the transducer and depoling the crystal.

Since total average power depends on a number of factors such as voltage, duty cycle and transducer electrical impedance, the following equations can be used to estimate the maximum excitation duration as well as the number of cycles in a burst to stay within the total power limitation:

Eqn. 18

$$V_{rms} = 1/2(0.707)V_{p-p}$$

Eqn. 19

$$P_{tot} = \frac{(Duty\ Cycle)(V_{rms})^2 \cos(\text{phase angle})}{Z}$$

Eqn. 20

$$\text{No. of Cycles in a Burst} = \frac{(\text{Freq.})(\text{Duty Cycle})}{\text{Rep Rate}}$$

Following is an example of how to use the above equations to calculate a duty cycle and number of cycles for a V310-SU transducer.

V310-SU
Assuming:

5.0 MHz, 0.25 in. element diameter, unfocused
100 V Peak-to-Peak

50 ohm nominal impedance at the transducer input
impedance (Note: This value will vary from transducer to
transducer and should be measured. An impedance plot can
be ordered at the time of purchase if necessary.)

-45° Phase Angle
5 kHz Rep Rate

Step 1: Calculate V_{rms}

$$V_{rms} = \frac{1}{2}(0.707)V_{p-p}$$

$$V_{rms} = \frac{1}{2}(0.707)(100) = 35.35 \text{ V}$$

Rearrange Equation (19) to solve for the Duty Cycle. Use
0.125 W as P_{tot} , as this is the maximum recommended for any
transducer.

$$\text{Duty Cycle} = \frac{Z \cdot P_{tot}}{(V_{rms})^2 \cdot \cos(\text{phase angle})}$$

$$= \frac{(50)(0.125)}{(35.35)^2 \cdot (\cos -45^\circ)}$$

$$= 0.007 \text{ s}$$

This means 7 milliseconds of excitation in every 1000
milliseconds.

Step 3: Number of cycles in the burst can now be calculated from
Equation (20).

$$\text{No. Of Cycles in Burst} = \frac{(\text{Freq.})(\text{Duty Cycle})}{\text{Rep Rate}}$$

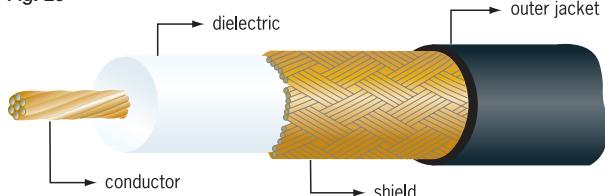

$$= (5 \cdot 10^6) \cdot (0.007) / (5 \cdot 10^3)$$

$$= 7$$

6. Cables

The inside of a cable is made of three main components. They are the conductor, the dielectric, and shield/braid. These components are then surrounded by an outer protective jacket. Figure (20) shows a cross-sectional view of a typical cable. The conductor acts as the positive connection of the cable while the shield acts as the ground. The dielectric isolates the conductor from the shield.

Fig. 20

Most cables have one shielding/braided layer. However, to better prevent electrical interference from the environment double shielded cables have an additional shielding/braided layer in contact with the other.

The following is a list of standard cable grades we offer:

Type	Grade	Impedance	Nominal Diameter
15	Low Impedance	15 ohms	0.11
25	Low Impedance	25 ohms	0.10
58	RG58/U	50 ohms	0.20
62	RG62/U	93 ohms	0.24
74	RG174/U	50 ohms	0.11
188	RG188/U	50 ohms	0.11
316	RG316/U	50 ohms	N/A

RG/U is the abbreviation for “radio guide, universal” in the military, “RG” is the designation for coaxial cable and “U” stands for “general utility”. Most of the cables used in ultrasonic NDT have military RG numbers that define the materials, dimensions, and electrical characteristics of the cables.

The characteristic impedance of a coaxial cable is determined by the ratio for the inner diameter of the outer conductor (D) to the outer diameter of the inner conductor (d) and by the dielectric constant (ϵ) of the insulating material between the conductors.

Eqn. 21

$$\text{Impedance } (Z_0) = \frac{138}{\sqrt{\epsilon}} \log \left(\frac{D}{d} \right) \Omega$$

The characteristic impedance can also be calculated from the capacitance (C) and the inductance (L) per unit length of cable

Eqn. 22

$$\text{Impedance } (Z_0) = \sqrt{\frac{L}{C}}$$

The most common values for coaxial cables are 50 ohm, 75 ohm, and 95 ohm. Note that the actual input impedance at a particular frequency may be quite different from the characteristics impedance of the cable due to the impedance of the source and load. In ultrasonics, on transmit the source is the pulser and the load is the transducer; on receive the source is the transducer and the load is the receiver. The complex impedance of the pulser and the transducers will reflect some of the electrical energy at each end of the cable. The amount of reflection is determined by the length of the cable, the frequency of the RF signal, and the electrical impedance of the cable and its termination. In ultrasonic NDT the effect of the cable is most practically determined by experimenting with the shorter and longer cables, with cables of differing impedance, and by placing a 50 ohm feed-through attenuator at the pulser/receiver jack.

7. Near Field Distances of Flat Transducers in Water

Table 1 – Near Field Distance of Flat Transducers in Water

Frequency (MHz)	Element Diameter (in.)	N	Focal Length (PTF)**	
			Min. (in.)	Max. (in.)
0.5	1.50	4.757	2.15	3.80
	1.125	2.661	1.50	2.10
	1.00	2.095	1.25	1.65
	0.75	1.164	0.78	0.93
1.0	1.50	9.559	2.50	7.65
	1.125	5.366	1.90	4.30
	1.00	4.235	1.625	3.38
	0.75	2.372	1.00	1.90

	0.25	3.935	0.50	3.15‡
20	0.25	5.247	0.50	4.20‡
	0.125	1.290	0.25	1.00‡
25	-	6.559	0.50	5.25‡

** Panametrics® Standard Case Style, Large Diameter Case Style, Slim Line Case Style, and Pencil Case Style Immersion Transducers with straight connectors (see "Immersion Transducers" starting on page 48) can be focused between the Minimum and Maximum Point Target Focal (PTF) distance limits listed in Table 1. Please consult Olympus before ordering a transducer focused outside these limits.

‡ Consideration should be given to attenuation effects which increase linearity and with the square of frequency and the square of bandwidth. In applications where long water paths are required the effects of frequency dependent attenuation should be checked per ASTM E 1065 Annex A7. It is advisable to consider the effects of frequency dependent attenuation if the focal distance equals or exceeds the following values:

The near field values in this table have been determined using the following equation:

$$N = \frac{D^2}{4\lambda} [1 - (\frac{\lambda}{D})^2]$$

Note that equations 8 and 8a on page 45 were derived from this expression. The calculations were carried out assuming an ultrasonic velocity in water of 0.586×10^5 in./s at 22 °C and using the actual transducer element diameters. It should be noted that the actual transducer element diameters are slightly smaller than the nominal element diameters listed in the tables in the catalog. The minimum and maximum practical focal lengths have been calculated by considering the acoustic and mechanical limitations of each configuration. These limitations are a function of transducer frequency, element diameter, and case dimensions. There may be exceptions to the limits listed in the table.

Frequency MHz	Focal Length in.
5.0	13
7.5	6
10	3.5
15	1.5
20	0.8
25	0.5
30	0.4

8. Acoustic Properties of Materials

Table 2 – Acoustic Properties of Materials

Material	Longitudinal Velocity		Shear Velocity		Acoustic Impedance (kg/m ² s × 10 ⁹)
	(in/μs)*	(m/s)	(in/μs)*	(m/s)	
Acrylic resin (Perspex)	0.107	2,730	0.056	1,430	3.22
Aluminum	0.249	6,320	0.123	3,130	17.06
